State and Regional Life Tables

1939-41

(Life tables for the white population of the United States,
each State, and certain groups of States, by sex)

Prepared in the Statistical Bureau of the
Metropolitan Life Insurance Company

Federal Security Agency
Oscar R. Ewing, Administrator

Public Health Service
Leonard A. Scheele, Surgeon General

National Office of Vital Statistics
Halbert L. Dunn, Chief

The 1939-41 life tables for individual States which are made available in this publication will fill a need often expressed by students of population trends, State public health and vital registration authorities, and those responsible for financial operation of pension schemes. As it was not feasible, because of wartime shortages of personnel and equipment, for the National Office of Vital Statistics to prepare such tables, it is indeed gratifying that the Metropolitan Life Insurance Company has found it possible to carry out this project.

HALBERT L. DUNN, M. D.

CHIEF, NATIONAL OFFICE
OF VITAL STATISTICS

FOREWORD

The following life tables for individual States and geographic sections of the country are based upon the census of population taken April 1, 1940, and the deaths recorded during the period 1939-41. They were computed in the Statistical Bureau of the Metropolitan Life Insurance Company. As these life tables constitute a valuable public document bearing upon the vital statistics of the nation, it is fitting that they should be issued by the National Office of Vital Statistics.

These life tables are unique in several respects. It is the first time our country will have on record a life table for each State. An earlier series, based upon the census of 1930 and the deaths recorded during 1929-31, lacked a life table for Texas, while that for South Dakota was based on deaths for 1930 alone. This earlier series, also prepared in the Statistical Bureau of the Metropolitan Life Insurance Company, was published in "Population Statistics; No. 2, State Data," by the National Resources Committee, October 1937. The two series differ in one other important respect; whereas that for 1929-31 was based upon deaths recorded by place of occurrence, the series for 1939-41 is based upon deaths allocated to place of residence.

These life tables focus attention on the wide variation in longevity and mortality still existing within the United States. Nebraska ranked highest in expectation of life at birth in 1939-41, with a figure of 66.25 years for white males, and 70.04 years for white females. On the other hand, Arizona ranked lowest on the list for white males, with an expectation of life at birth of only 56.83 years, and New Mexico ranked lowest for white females, with 60.96 years. It is interesting to note, however, that the gain in expectation of life at birth from 1929-31 to 1939-41 was greater in Arizona and New Mexico than in Nebraska. As a result, there has been a narrowing in the margin in longevity and mortality between the States with the poorest and the best records.

The method used in constructing the life tables for 1929-31 is described in "Length of

Life," by Dublin and Lotka (1936); the life tables for 1939-41 were computed essentially by the procedure adopted by T. N. E. Greville for the "United States Life Tables and Actuarial Tables, 1939-1941," Bureau of the Census, 1946. A notable feature in the computation of the life tables for individual States and sections of the country for 1939-41 is the extensive use made of punch-card tabulation machinery. Except for the mortality rates at the first few ages of life, the entire computation was performed by this means. In addition, the life table functions were listed on a tabulating machine in such a manner that they could be reproduced directly for publication. The use of punch-card machinery thus effected an appreciable saving in expense and time for both the computation and the reproduction of the final life tables. It is planned to publish elsewhere an account of the sources of the data for these tables, their characteristics, and some of the features of their construction.

The life tables for the individual States and sections of the country for 1939-41, as well as those for 1929-31, were prepared under the direction of Mortimer Spiegelman, Fellow of the Actuarial Society of America and of the American Institute of Actuaries. The punch-card operations were under the supervision of Mr. Maurice L. Goldstein; the details of these operations were devised by Mr. Salvator B. Palazzo. Much credit is due them for bringing this sizable operation to completion. During the course of the computations, Dr. Thomas N. E. Greville of the National Office of Vital Statistics was consulted on technical problems requiring special attention. His valuable suggestions are gratefully acknowledged. To Dr. Halbert L. Dunn, Chief of the National Office of Vital Statistics, thanks are due for furnishing unpublished data necessary for the preparation of the life tables.

Louis I. Dublin

Second Vice-President and Statistician
Metropolitan Life Insurance Company

EXPLANATION OF THE TABLES

Both the descriptive titles and the conventional actuarial symbols appear at the head of the columns in each of the tables. The description which follows gives a more detailed explanation of each column of the life table.

Column 1—Year of age (x to $x+1$).—The year of age, shown in column 1, is the interval between two successive birthdays. For instance, "4-5" indicates the interval between the fourth birthday and the fifth, in other words, the fifth year of life.

Column 2—Mortality rate ($1000q_x$).—This column shows the number of deaths within 1 year after the birthday indicated, among 1,000 persons alive on that birthday. For example, the rate of mortality at age 45 for white males in the State of Pennsylvania (see table on page 214) is 8.31 per 1,000. In other words, during 1939-41, 8.31 out of every 1,000 white males in Pennsylvania who were alive on their forty-fifth birthday died before reaching age 46. The rates of mortality form the basis of the life table, all the other columns being derived from them.

Column 3—Number living (I_x).—This column shows the number of persons who would survive to each age out of a cohort of 100,000 live births, subject throughout life to the rates of mortality shown in column 2. Thus, the table on page 214 shows that out of 100,000 white male babies born alive in Pennsylvania, 95,281 will complete the first year of life and enter the second; 94,880 will begin the third year; 92,422 will reach age 21; and 30,491 will live to age 75.

Column 4—Number dying (d_x).—This column shows the number dying in each successive year of age out of 100,000 live births. Out of 100,000 white males born alive in Pennsylvania, 4,719 die in the first year of life, 401 in the second year, 177 in the twenty-first year, and 2,715 in the seventy-fifth year. Each figure in column 4 is the difference between

two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x).—Suppose that a group of 100,000 individuals like that assumed in columns 3 and 4 is born every year, and that the rates of mortality in each such group at each age throughout the lives of the members are exactly those shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would make up what is called a stationary population—stationary because in such a population the number of persons living in any given age group would never change. When an individual left the group, either by death or by growing older and entering the next higher age group, his place would immediately be taken by someone entering from the next lower age group. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who, each year, reach the birthday indicated in column 1, while column 4 shows the number who die each year in the indicated age interval.

Column 5 shows the number of persons in the stationary population in the indicated age interval. For example, the figure given for white males in Pennsylvania in the year of life 45-46 is 84,191. This means that in a stationary population of white males supported by 100,000 annual births and subject always to the rates of mortality shown in column 2, a census taken on any date would show 84,191 persons between exact ages 45 and 46.

Column 6 shows the total number of persons in the stationary population (column 5) in the indicated age interval and all subsequent age intervals. For example, in the stationary population of white males referred to in the last illustration, column 6 shows

EXPLANATION OF THE TABLES

9

that there would be at any given moment a total of 2,104,316 persons who have passed their forty-fifth birthday. The population at all ages 0 and above (in other words, the total population of the stationary community) would be 8,219,952.

Column 7—Average future lifetime (δ_x).—The average future lifetime (also called the complete expectation of life) at any age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of mortality rates. The values in column 5 of the life tables can also be interpreted in terms of a single life table cohort, without introducing the concept of the stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 84,191 for white males in Pennsylvania in the year of life 45-46 is the total number of years that will be lived between the forty-fifth and forty-sixth birthdays by the 84,542 (column 3) who reach their forty-fifth birthday out of 100,000 white males born alive. The corresponding figure in column 6 (2,104,316) is the total number of years that will be lived after attaining age 45 by the 84,542 reaching that age. This number of years divided by the number of persons (2,104,316 divided by 84,542) gives 24.89 as

the average future lifetime at age 45 of white males in Pennsylvania.

In comparing life table values for different States, the reader should bear in mind that the computations were based on reported deaths, without correction (except in the first year of life) for possible incomplete reporting. As there may be considerable variation among the States in the extent of nonreporting, the values of the average future lifetime for a given State would be somewhat overstated, relative to the corresponding values for States having more complete reporting. Similar considerations would apply to the comparison of other life table values. While no specific information is available as to the relative completeness of death registration in the different States, a study of the completeness of the birth registration was made in connection with the 1940 census,¹ and it is thought probable that the relative completeness of reporting of deaths from State to State closely parallels that of births.

¹Percentages of completeness for each State are given in the publication: "Studies in Completeness of Birth Registration. Part I. Completeness of Birth Registration, United States, December 1, 1939 to March 31, 1940," Vital Statistics—Special Reports, vol. 17, No. 18, April 20, 1943.
