Technical Notes on Nesting and Weight Variables

The design of the 2004 National Nursing Home Survey entailed multi-stage sampling, each stage involving sampling within a defined grouping or cluster. The current resident public-use file includes the nest variables of the sampling framework for use in statistical software that accounts for complex sample designs in the estimation of variances and standard errors. Proper adjustment of standard errors for stratified or clustered sampling provides the analyst with accurate significance tests.

The nest variables or sampling stages in the current resident file are RSTRATA and FACNUM. The sampling weight which represents each observation's contribution in the estimation of the current resident population is SAMWT.

In the statistical software, SUDAAN, the analyst can use the design option WOR for sampling without replacement. When using SUDAAN for WOR, the variables for the TOTCNT statement in SUDAAN are POPFAC and NPOPRES. Below are the SUDAAN statements for the NEST and TOTCNT statements for the current resident public use file with WOR. The example uses the crosstab procedure to illustrate.

proc crosstab data=[file name] design= WOR; nest rstrata facnum / missunit; totcnt popfac npopres; weight samwt;

Note on categorical variables for Activities of Daily Living (ADL) with values of zero:

Questions on ADLs that were derived from the Long-Term Care MDS (Minimum Data Set) resident assessment form follow the coding scheme used in the MDS form. Following that scheme, the category "Independent" is coded as "0." In SUDAAN, the "0" values are treated as a legitimate value or category when using the CLASS statement. In contrast, the "0" is not treated as a legitimate value, but rather as missing, when the SUBGROUP and LEVELS statements are used. If the SUBGROUP and LEVELS statements are used instead of the CLASS statement, the user would need to recode the respective ADL variables to conform with the parameters of the functions of the SUBGROUP and LEVELS statements.

Note on cases with imputed age:

The variable AGEIMP indicates cases where age was imputed. For each case in which age was imputed, similar cases in the sample with age known were selected with one randomly choosen from the group of similar cases. The known age of the selected case was then assigned to the case with age originally missing. The algorithm for selecting similar cases involved assessment of the match on the following characteristics: resident gender, length of stay, dependency on activities of daily living, facility ownership, bed size, region, and metropolitan status of the facility.

Note on cases with imputed race:

The variable RACEIMP indicates cases where race was imputed. For each case in which race was imputed, similar cases in the sample with race known were selected with one randomly choosen from the group of similar cases. The known race of the selected case was then assigned to the case with race originally missing. The algorithm for selecting similar cases involved assessment of the match on the following characteristics: resident gender, marital status, ethnicity (Hispanic or Non-Hispanic), facility ownership, bed size, state (then region if state did not match), and metropolitan status of the facility.

Frequency of Sampled Cases for Selected Variables

Frequencies of selected variables at different locations in the file layout are reported below to assist the analyst in verifying the integrity of the data file and layout used. The number (n) of records in the current resident public-use file with the respective values for SEX, RACEWHT, LIVCHILD, COMOTOSE, BATH, ANYFALLS, ANYDVICE, RDEMEN, HOSPADM, PRN, LEGAL, OXYGEN, MCAID1, SAMEBILL, METRSTAT, OWNERSHP, and BEDSIZE are as follows:
