LIFE TABLES FOR THE GEOGRAPHIC DIVISIONS OF THE UNITED STATES: 1959-61

INTRODUCTION

This report contains the 1959-61 life tables for the nine geographic divisions of the United States. Separate life tables are presented by color and sex for each geographic division—a total of 36 tables. The geographic divisions and the States they include are as follows:

NEW ENGLAND
- Maine
- New Hampshire
- Vermont
- Massachusetts
- Rhode Island
- Connecticut

MIDDLE ATLANTIC
- New York
- New Jersey
- Pennsylvania

EAST NORTH CENTRAL
- Ohio
- Indiana
- Illinois
- Michigan
- Wisconsin

WEST NORTH CENTRAL
- Minnesota
- Iowa
- Missouri
- North Dakota
- South Dakota
- Nebraska
- Kansas

SOUTH ATLANTIC
- Delaware
- Maryland
- District of Columbia
- Virginia
- West Virginia

SOUTH ATLANTIC—Con.
- North Carolina
- South Carolina
- Georgia
- Florida

EAST SOUTH CENTRAL
- Kentucky
- Tennessee
- Alabama
- Mississippi

WEST SOUTH CENTRAL
- Arkansas
- Louisiana
- Oklahoma
- Texas

MOUNTAIN
- Montana
- Idaho
- Wyoming
- Colorado
- New Mexico
- Arizona
- Utah
- Nevada

PACIFIC
- Washington
- Oregon
- California
- Alaska
- Hawaii

These tables are based on the 1960 Census of Population and on the average annual number of resident deaths during the 3-year period 1959-61. For ages under 2, because enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics at these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have been adjusted to make the numbers progress smoothly with increasing age. Therefore the figures at ages 85 and over may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85 which were used in the calculation of the life tables are known to be subject to certain errors. However, the only error considered serious enough to require adjustment prior to the calculation of the life tables was the apparent inaccuracy in age reporting among nonwhite persons who were about 60 years old. In order to avoid anomalous life table values, the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, through sucessive ages, to the mortality rates observed in a certain population or population subdivision during a specified period. For example, table 1 is a life table for white males in New England; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive ages, to the average annual mortality rates observed among white males in New England in the 3-year period 1959-61. One of the columns in this table shows the average number of years of life remaining to those in the cohort who reach each age. The text table below gives the average remaining lifetime at selected ages for the United States and the nine geographic divisions according to the 1959-61 life tables. Values are shown at birth and at ages 25 and 65 for white and nonwhite males and females.

AVERAGE REMAINING LIFETIME IN YEARS AT SPECIFIED AGES, BY RACE AND SEX: UNITED STATES AND EACH GEOGRAPHIC DIVISION, 1959-61

AREA	AT BIRTH				AT AGE 25				AT AGE 65			
	White		Nonwhite		White		Nonwhite		White		Nonwhite

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

(Figures used for illustration are from table 1)

Column 1—Age interval (x to $x + t$).—The age interval shown in column 1 is the interval between the two exact ages indicated. For instance, "3-28 days" means the 25-day interval between the exact ages of 3 days and 28 days, and "43-44 years" means the interval of 1 year between the 43d and 44th birthdays. In the life tables in this report the age interval is always 1 year except in the case of subdivisions of the first year of life.

Column 2—Proportion dying ($_tq_x$).—This column shows the proportion of the cohort alive at the beginning of the indicated age interval who will die before reaching the end of the age interval (in most instances, the next birthday). For example, for white males in New England (table 1) in the age interval 3-28 days, the proportion dying is .00364—out of every 1,000 white male babies surviving 3 days after birth, 3.64 will die before reaching the age of 28 days. Similarly, for the age interval 43-44 years, the proportion dying is .00430; on the basis of the mortality rates of 1959-61 for white males in New England, out of every 1,000 reaching their 43d birthday, 4.30 will die before reaching their 44th birthday. When the age interval is 1 year, the symbol q_x (instead of $(_1q_x)$ is generally used for the proportion dying.

Column 3—Number surviving (l_x).—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the exact age marking the beginning of the indicated age interval. Out of 100,000 babies born alive in the cohort shown in table 1, 98,438 will survive 3 days, 97,488 will complete the first year of life and enter the second, 96,074 will reach age 21, and 39,039 will live to age 75.

Column 4—Number dying ($_td_x$).—This column shows the number dying in each successive age interval out of 100,000 live births. Out of 100,000 born alive in the cohort shown in table 1, 358 will die between the ages of 3 and 28 days, 2,512 will die during the first year of life, and 397 will die during the year between their 43d and 44th birthdays. Each figure in column 4 is the difference between two consecutive figures in column 3. When the age interval is 1 year, the symbol d_x (instead of $_td_x$) is generally used for the number dying.

Columns 5 and 6—Stationary population ($_tL_x$ and T_x).—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportions dying in each such group in each age interval throughout the

lives of the members are exactly those shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given age interval would never change. When an individual left an age interval, whether by death or by growing older and entering the next higher age interval, his place would immediately be taken by someone entering from the next lower age interval. Thus, a census taken at any time in such a stationary community would always show the same total population among the various age intervals. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who, each year, reach the exact age that marks the beginning of the age interval indicated in column 1, and column 4 shows the number of persons who die each year in the indicated age interval.

Column 5, ${}_tL_x$, shows the number of persons in the stationary population in the indicated age interval. For example, the figure shown in table 2 for 3-28 days is 6,724. This means that in a stationary population supported by 100,000 annual births and with proportions dying in each age interval always in accordance with column 2 a census taken on any date would show 6,724 persons between the exact ages of 3 and 28 days. Similarly, the figure for the age interval 43-44 years is 92,073. Thus the stationary population described would always contain 92,073 persons between their 43d and 44th birthdays. When the age interval is 1 year, the symbol L_x is generally used instead of ${}_1L_x$.

Column 6, T_x, shows the total number of persons in the stationary population (column 5) in the indicated age interval and all subsequent age intervals. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment a total of 6,764,941 persons who have survived at least 3 days following birth and a total of 2,651,300 persons who have attained age 43. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,765,754.

Column 7—Average remaining lifetime ($\mathring{e}_x$).—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 of the life tables can also be interpreted in terms of a single life table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between two indicated exact ages by all those reaching the earlier age among the survivors of a cohort of 100,000 live births. Thus the figure 6,724 for white males in New England in the age interval 3-28 days is the total number of years of life lived between the exact ages of 3 and 28 days by the 98,438 (column 3) who reached the exact age of 3 days out of 100,000 born alive.

The corresponding figure (6,764,941) in column 6 is the total number of years lived after attaining the age of 3 days by the 98,438 reaching that exact age. Similarly, the figure 92,073 in column 5 for the age interval 43-44 is the total number of years lived between the 43d and 44th birthdays by the 92,271 (column 3) who reached the 43d birthday out of the original cohort of 100,000. The corresponding figure (2,651,300) in column 6 is the total number of years lived after attaining age 43 by the 92,271 reaching that age. This number of years divided by the number of persons (2,651,300 divided by 92,271) gives 28.73 years as the average remaining lifetime at age 43. A similar division of 6,764,941 by 98,438 gives 68.72 years as the average remaining lifetime at the age of 3 days.

TABLE 1. LIFE TABLE FOR WHITE MALES: NEW ENGLAND DIVISION, 1959-61

AGE INTERVAL	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
