## Abstract

The life tables in this report are current abridged life tables for the United States based on age-specific death rates in 1995. The data used to prepare these abridged life tables are 1995 final mortality statistics and July 1, 1995, population estimates. Presented are tables showing life expectancy and survivorship by age, race, and sex. In 1995 the overall expectation of life at birth was 75.8 years, an increase of 0.1 year compared with life expectancy in 1994. Increases in life expectancy from 1994 to 1995 were also noted for white males (from 73.3 to 73.4) and black males (from 64.9 to 65.2). Life expectancy for white and black females did not change from 1994 to 1995.

## Introduction

Death rates for a specific period may be summarized by the life table method to obtain measures of comparative longevity. There are two types of life tables—the generation or cohort life table and the current life table.

The generation life table provides a “longitudinal” perspective in that it follows the mortality experience of a particular cohort, all persons born in the year 1900, for example, from the moment of birth through consecutive ages in successive calendar years. Based on age-specific death rates observed through consecutive calendar years, the generation life table reflects the mortality experience of an actual cohort from birth until no lives remain in the group. To prepare just a single complete generation life table requires data over many years. It is not feasible to construct generation life tables entirely on the basis of actual data for cohorts born in this century (1). It is necessary to project data for the incomplete period for cohorts whose life spans are not yet complete (2).

The better-known current life table may, in contrast, be characterized as “cross-sectional.” Unlike the generation life table, the current life table does not represent the mortality experience of an actual cohort. Rather, the current life table considers a hypothetical cohort and assumes that it is subject to the age-specific death rates observed for an actual population during a particular period. Thus, for example, a current life table for 1995 assumes a hypothetical cohort subject throughout its

lifetime to the age-specific death rates prevailing for the actual population in 1995. The current life table may thus be characterized as rendering a “snapshot” of current mortality experience, and shows the long-range implications of a set of age-specific death rates that prevailed in a given year. In this report the term “life table” refers only to the current life table and not to the generation life table.

## Data and methods

The data used to prepare the abridged U.S. life tables for 1995 are final mortality statistics and the July 1, 1995, population estimates by age, race, and sex prepared by the U.S. Bureau of the Census (see [Technical notes](#)). These life tables are constructed by reference to a “standard” table (see [Technical notes](#)).

*Expectation of life*—The most frequently used life table statistic is life expectancy ( ${}^o e_x$ ), which is the average number of years of life remaining for persons who have attained a given age ( $x$ ). Life expectancy and other life table values at specified ages in 1995 are shown for the total population and by race and sex in [table 6-1](#). In addition, life expectancies at single years of age by race and sex are shown in [table 6-3](#).

Life expectancy at birth for 1995 for the total population was 75.8 years. This represents the average number of years that the members of the life table cohort may expect to live at the time of birth ([table 6-1](#)).

*Survivors to specified ages*—Another way of assessing the longevity of the life table cohort is by determining the proportion who survive to specified ages. The  $l_x$  column of the life table provides the data for computing the proportion. For instance, 80,279 persons out of the original 1995 life table cohort of 100,000 (or 80.3 percent) were alive at exact age 65 ([table 6-2](#)).

## Explanation of the columns of the life table

*Column 1—Age interval ( $x$  to  $x + n$ )*—This column shows the age interval between the two exact ages indicated. For instance, “20–25” means the 5-year interval between the 20th and 25th birthdays.

*Column 2—Proportion dying ( ${}_n q_x$ )*—This column shows the proportion of the cohort who are alive at the beginning of an indicated age interval and who will die before reaching the end of that age interval. For example, for males in the age interval 20–25 years, the proportion dying is 0.00806: Out of every 1,000 males alive and exactly 20 years of age at the beginning of the period, about 8 will die before reaching their 25th birthday. In other words, the  ${}_n q_x$  values represent probabilities that persons who are alive at the beginning of a specific age

---

NOTE: This report was prepared in the Division of Vital Statistics. Robert N. Anderson, Mortality Statistics Branch, wrote this report under the general direction of Harry M. Rosenberg, Chief of the Mortality Statistics Branch. Thomas D. Dunn provided content review. Charles E. Royer provided computer programming support. Registration Methods staff and the Data Acquisition and Evaluation Branch provided consultation to State vital statistics offices regarding collection of the death certificate data on which this report is based. This report was edited by Demarius V. Miller and typeset by Zung T. N. Le of the Publications Branch, Division of Data Services.

interval will die before reaching the beginning of the next age interval. The “proportion dying” column forms the basis of the life table. The life table is so constructed that all other columns are derived from it.

*Column 3—Number surviving ( $l_x$ )*—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the exact age marking the beginning of each age interval. The  $l_x$  values are computed from the  ${}_nq_x$  values, which are successively applied to the remainder of the original 100,000 persons still alive at the beginning of each age interval. Thus out of 100,000 male babies born alive, 99,169 will complete the first year of life and enter the second; 98,993 will begin the sixth year; 98,144 will reach age 20; and 24,190 will live to age 85.

*Column 4—Number dying ( ${}_nd_x$ )*—This column shows the number dying in each successive age interval out of 100,000 live births. Out of 100,000 males born alive, 831 will die in the first year of life; 176 in the succeeding 4 years; 791 in the 5-year period between exact ages 20 and 25, and 24,190 will die after reaching age 85. Each figure in column 4 is the difference between two successive figures in column 3.

*Columns 5 and 6—Stationary population ( ${}_nL_x$  and  $T_x$ )*—Suppose that a group of 100,000 individuals like that assumed in columns 3 and 4 is born every year and that the proportions dying in each such group in each age interval throughout the lives of the members are exactly those shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would make up what is called a stationary population—stationary because in such a population the number of persons living in any given age group would never change. When individuals left the group, either by death or by growing older and entering the next higher age group, their places would immediately be taken by persons entering from the next lower age group. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various age groups. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who, each year, reach the birthday that marks the beginning of the age interval indicated in column 1, and column 4 shows the number of persons who die each year in the indicated age interval.

Column 5 shows the number of persons in the stationary population in the indicated age interval. For example, the figure given for males in the age interval 20–25 years is 488,785. This means that in a stationary population of males supported by 100,000 annual births and with proportions dying in each age group always in accordance with column 2, a census taken on any date would show 488,785 persons between exact ages 20 and 25 years.

Column 6 shows the total number of persons in the stationary population (column 5) in the indicated age interval and all subsequent age intervals. For example, in the stationary population of males referred to in the last illustration, column 6 shows that there would be at any given moment a total of 5,277,537 persons who have passed their 20th birthday. The male population at all ages 0 and above (the total male population of the stationary community) would be 7,254,216.

*Column 7—Average remaining lifetime ( ${}^e_x$ )*—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age on the basis of a given set of age-specific rates of dying. To arrive at this value, it is first necessary to observe that the figures in column 5 of the life table can also be interpreted in terms of a single life table cohort without introducing the concept of the stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between two indicated birthdays by all those reaching the earlier birthday. Thus, the figure 488,785 for males in the age interval 20–25 is the total number of years lived between the 20th and 25th birthdays by the 98,144 (column 3) who reached the 20th birthday out of 100,000 males born alive. The corresponding figure 5,277,537 in column 6 is the total number of years lived after attaining age 20 by the 98,144 reaching that age. This number of years divided by the number of persons (5,277,537 divided by 98,144) gives 53.8 years as the average remaining lifetime of males at age 20.

## Results

The expectation of life at birth for 1995 represents the average number of years that a group of infants would live if the infants were to experience throughout life the age-specific death rates prevailing in 1995. In 1995 the average expectation of life at birth was 75.8 years, an increase of 0.1 year compared with life expectancy in 1994 and matches the high of 75.8 years recorded in 1992. The increase between 1994 and 1995 represents the continuation of the general upward trend in U.S. life expectancy observed throughout this century.

In 1995 life expectancy for females was 78.9 years, a decrease of 0.1 year from 1994. Life expectancy was 72.5 years for males, a 0.1-year increase from 1994 to 1995. The difference in life expectancy between the sexes was 6.4 years in 1995, a slight narrowing from the difference (6.6) in the previous year. In contrast to the widening gap from 1900 to 1975 (2.0 years in 1900, 5.5 years in 1950, and 7.8 years in 1975), the difference in life expectancy between the sexes narrowed between 1979 and 1988 (7.8 years in 1979, 7.1 years in 1984, and 6.9 years in 1988) and between 1990 (7.0 years) and 1995 (6.4 years).

Between 1994 and 1995, life expectancy for the white population remained static at 76.5 years, while for the black population it increased 0.1 year from 69.5 years to 69.6 years, equaling the record high reached in 1992. The difference in life expectancy between the white and black populations was 6.9 years in 1995, a slight narrowing of the gap from 1993 (7.1 years) and 1994 (7.0 years). Although the white-black difference in life expectancy narrowed from 7.6 years in 1970 to 5.7 years in 1982, it increased to 7.1 years in 1989 before declining to 7.0 years in 1990 and 1991, and 6.9 years in 1992.

Among the four race-sex groups (figure 1), white females continued to have the highest life expectancy at birth (79.6 years), followed by black females (73.9 years), white males (73.4 years), and black males (65.2 years). Between 1994 and 1995, life expectancy increased 0.1 year for white males (from 73.3 in 1994 to 73.4 in 1995) and 0.3 years for black males (from 64.9 in 1994 to 65.2 in 1995). Black males experienced

an unprecedented decline in life expectancy every year for 1984–89 (3), but an annual increase in 1990–92, 1994, and 1995. However, by 1995 life expectancy for black males was still 0.1 year less than the peak life expectancy of 65.3 years attained in 1984. For white females life expectancy increased nearly every year from 1970 to 1992 when it reached a record high of 79.8 years. Since 1992 white female life expectancy has declined by 0.2 years. From 1970 to 1992 life expectancy for black females also generally increased. Since 1992 black female life expectancy has remained virtually unchanged. Overall, the largest gain in life expectancy between 1980 and 1995 was for white males (2.7 years), followed by white females (1.5 years), and black males and females (1.4 years each).

The 1995 life table may be used to compare life expectancies at any age from birth onward. On the basis of mortality experienced in 1995, a person aged 50 years could expect to live an average of 29.3 more years for a total of 79.3 years, and a person aged 65 years could expect to live an average of 17.4 more years for a total of 82.4 years (table 6-1).

## Technical notes

*The life table program*—Three series of life tables are prepared by the National Center for Health Statistics—complete, preliminary abridged, and final abridged. The complete life tables for the U.S. population are based on decennial census data and deaths for a 3-year period around the census year. Preliminary abridged life tables are based on a substantial sample (approximately 90 percent) of death records. Estimates of life expectancy from the preliminary series are published biannually. The final abridged life tables (referred to in this section as “abridged life tables”) are based on a complete count of all reported deaths.

Available annually since 1945, the final abridged life tables are based on deaths occurring during the calendar year and on midyear postcensal population estimates provided by the U.S. Bureau of the Census. Beginning with 1945, abridged life tables have been constructed by reference to a standard table (4). Methodology developed by Greville was used in constructing life tables for 1945–52. Since 1953 a modified method has been employed (5). U.S. life tables for the decennial period 1979–81 are used as the standard table in constructing the 1995 abridged life tables.

*Geographic coverage*—The geographic areas covered in life tables before 1929–31 were limited to the death-registration areas. Life tables for 1900–1902 and 1909–11 were constructed using mortality data from the 1900 death-registration States (10 States and the District of Columbia) and for 1919–21 from the 1920 death-registration States (34 States and the District of Columbia). The tables for 1929–31 through 1958 cover the conterminous United States. Decennial life table values for the 3-year period 1959–61 were derived from data that include both Alaska and Hawaii for each year (table 6-4). Data for each year shown in table 6-5 include Alaska beginning in 1959 and Hawaii beginning in 1960. However, it is not believed that the inclusion of these two States materially affects life table values.

**Figure 1. Life expectancy by race and sex: United States, 1970–95**

*Revised life table values, 1961–89*—Life table values for 1960–69, 1970–79, and 1980–89 are constructed using the U.S. decennial life tables for 1959–61, 1969–71, and 1979–81, respectively, as the standard tables. The life table values for 1981–89 appearing in this publication are based on revised intercensal estimates of the populations for those years. As a result, the life table values for 1981–89 may differ from the life table values for those years published in *Vital Statistics of the United States* for 1989 and earlier years.

*New Jersey data, 1962–64*—The life tables for 1962 and 1963 for the six population groups involving race do not include data from New Jersey, which omitted the item on race from its certificates of live birth, death, and fetal death in use at the beginning of 1962. The item was restored during the latter part of 1962. However, the certificate revision without this item was used for most of 1962 as well as for 1963. For computing vital rates, populations by age, race, and sex (excluding New Jersey) were estimated to obtain comparable denominators. Approximately 7 percent of the New Jersey death records for 1964 did not contain the race designation. When the records were being electronically processed for this State, the “race not stated” deaths were allocated to white or to black.

*Nonresidents*—Beginning in 1970 the deaths of nonresidents of the United States have been excluded from the life table statistics.

*Estimates for single calendar years*—Annual abridged life tables were initiated in 1945 for white males, white females, all other males, and all other females. The figures in table 6-5 by race and sex for the following years were estimated using a procedure other than the abridged life table methodology (6).

Years	Race and sex
1900–45	Total
1900–47	Male
1900–47	Female
1900–50	White
1900–44	White male
1900–44	White female
1900–50	All other
1900–44	All other male
1900–44	All other female

*Population bases for computing life tables*—The population used for computing life table values shown in this section (furnished by the U.S. Bureau of the Census) represents the resident population of the United States. The populations used for computing the 1995 life table values are based on the July 1, 1995, population estimates that are consistent with the 1990 census (7). The 1990 census counts by race and age were modified. Race was modified to be consistent with the Office of Management and Budget categories and historical categories for mortality data. The modification procedures for race and age are described in a census report (8).

SECTION 6 – LIFE TABLES – PAGE 8

Table 6-1. Abridged Life Tables by Race and Sex: United States, 1995—Con.  
(Page 4 of 4)

Age interval  Period of life between two exact ages stated in years, race, and sex  (1)	Proportion dying	Of 100,000 born alive		Stationary population		Average remaining lifetime
	Proportion of persons alive at beginning of age interval dying during interval  (2)	Number living at beginning of age interval  (3)	Number dying during age interval  (4)	In the age interval  (5)	In this and all subsequent age intervals  (6)	Average number of years of life remaining at beginning of age interval  (7)

SECTION 6 – LIFE TABLES – PAGE 13

Table 6-4. Life Table Values by Race and Sex: Death-Registration States, 1900-1902 to 1919-21, and United States, 1929-31 to 1995—Con.

(Page 3 of 6)

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929-31, data are for groups of registration States as follows: 1900-1902 and 1909-11, 10 States and the District of Columbia; 1919-21, 34 States and the District of Columbia. Beginning 1970 excludes deaths of nonresidents of the United States; see Technical Appendix.]

Age, race, and sex	Number of survivors out of 100,000 born alive ( <i>l<sub>x</sub></i> )

SECTION 6 – LIFE TABLES – PAGE 16

Table 6-4. Life Table Values by Race and Sex: Death-Registration States, 1900-1902 to 1919-21, and United States, 1929-31 to 1995—Con.  
(Page 6 of 6)

[Alaska and Hawaii included beginning in 1959. For decennial periods prior to 1929-31, data are for groups of registration States as follows: 1900-1902 and 1909-11, 10 States and the District of Columbia; 1919-21, 34 States and the District of Columbia. Beginning 1970 excludes deaths of nonresidents of the United States; see Technical Appendix]

SECTION 6 – LIFE TABLES – PAGE 18

Table 6-5. Estimated Average Length of Life in Years, by Race and Sex: Death-Registration States, 1900-28, and United States, 1929-95—Con.

(Page 2 of 2)

[For selected years, life table values shown are estimates; see Technical Appendix. Beginning 1970 excludes deaths of nonresidents of the United States; see Technical Appendix.]

Area and year	All races			White			All other					
	Both sexes	Male	Female	Both sexes	Male	Female	Total			Black		
							Both sexes	Male	Female	Both sexes	Male	Female
DEATH-REGISTRATION STATES												
1928 .....	56.8	55.6	58.3	58.4	57.0	60.0	46.3	45.6	47.0	---	---	---
