STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.73 years for total males and 75.08 for total females. This State ranks 30th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	27-8
2. Males -----	27-10
3. Females -----	27-12
4. White population -----	27-14
5. White males -----	27-16
6. White females -----	27-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00068—out of every 1,000 reaching their 21st birthday, 0.68 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,112 will complete the first year of life and enter the second, 96,823 will reach age 21, and 62,377 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,888 will die in the first year of life, 66 in the 22d year, and 2,372 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,790. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,790 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,460,250 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,508,298.

Column 7—Average remaining lifetime (e'_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,790 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,823 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,460,250) in column 6 is the total number of years lived after attaining age 21 by the 96,823 reaching that age. This number of years divided by the number of persons (5,460,250 divided by 96,823) gives 56.39 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MONTANA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.85 years for total males and 76.61 for total females. This State ranks 5th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	28-8
2. Males -----	28-10
3. Females-----	28-12
4. White population-----	28-14
5. White males -----	28-16
6. White females-----	28-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93
2	Minnesota-----	72.96	69.38	76.80	73.04	69.46	76.87	(1)	(1)	(1)

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00059—out of every 1,000 reaching their 21st birthday, 0.59 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,387 will complete the first year of life and enter the second, 97,411 will reach age 21, and 67,099 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,613 will die in the first year of life, 58 in the 22d year, and 2,460 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,382. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,382 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,603,648 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,660,676.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,382 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,411 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,603,648) in column 6 is the total number of years lived after attaining age 21 by the 97,411 reaching that age. This number of years divided by the number of persons (5,603,648 divided by 97,411) gives 57.53 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEBRASKA, 1969-71

AGE IN YEARS PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED (1)	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAIN- ING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 65.60 years for total males and 73.32 for total females. This State ranks 46th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	29-8
2. Males -----	29-10
3. Females-----	29-12
4. White population-----	29-14
5. White males -----	29-16
6. White females-----	29-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00126—out of every 1,000 reaching their 21st birthday, 1.26 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,067 will complete the first year of life and enter the second, 96,762 will reach age 21, and 58,374 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,933 will die in the first year of life, 123 in the 22d year, and 2,688 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,700. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,700 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,284,653 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,331,983.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,700 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,762 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,284,653) in column 6 is the total number of years lived after attaining age 21 by the 96,762 reaching that age. This number of years divided by the number of persons (5,284,653 divided by 96,762) gives 54.62 as the average remaining lifetime at age 21 for females in this State.

NEW HAMPSHIRE STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.48 years for total males and 75.19 for total females. This State ranks 20th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	30-8
2. Males -----	30-10
3. Females-----	30-12
4. White population-----	30-14
5. White males -----	30-16
6. White females-----	30-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00049—out of every 1,000 reaching their 21st birthday, 0.49 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,313 will complete the first year of life and enter the second, 97,503 will reach age 21, and 61,831 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,687 will die in the first year of life, 47 in the 22d year, and 2,741 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,480. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,480 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,462,761 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,519,040.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,480 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,503 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,462,761) in column 6 is the total number of years lived after attaining age 21 by the 97,503 reaching that age. This number of years divided by the number of persons (5,462,761 divided by 97,503) gives 56.03 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEW HAMPSHIRE, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

NEW JERSEY

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.52 years for total males and 74.38 for total females. This State ranks 21st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	31-6
2. Males -----	31-8
3. Females -----	31-10
4. White population -----	31-12
5. White males -----	31-14
6. White females -----	31-16
7. Population other than white -----	31-18
8. Males other than white -----	31-20
9. Females other than white -----	31-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00072—out of every 1,000 reaching their 21st birthday, 0.72 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,293 will complete the first year of life and enter the second, 97,409 will reach age 21, and 59,844 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,707 will die in the first year of life, 70 in the 22d year, and 2,823 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,374. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,374 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,382,745 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,438,087.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,374 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,409 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,382,745) in column 6 is the total number of years lived after attaining age 21 by the 97,409 reaching that age. This number of years divided by the number of persons (5,382,745 divided by 97,409) gives 55.26 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEW JERSEY, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.51 years for total males and 74.51 for total females. This State ranks 34th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	32-8
2. Males -----	32-10
3. Females -----	32-12
4. White population -----	32-14
5. White males -----	32-16
6. White females -----	32-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00114—out of every 1,000 reaching their 21st birthday, 1.14 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,115 will complete the first year of life and enter the second, 96,801 will reach age 21, and 61,254 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,885 will die in the first year of life, 110 in the 22d year, and 2,622 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,746. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,746 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,402,384 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,450,635.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,746 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,801 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,402,384) in column 6 is the total number of years lived after attaining age 21 by the 96,801 reaching that age. This number of years divided by the number of persons (5,402,384 divided by 96,801) gives 55.81 as the average remaining lifetime at age 21 for females in this State.

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.95 years for total males and 74.15 for total females. This State ranks 31st among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	33-6
2. Males -----	33-8
3. Females -----	33-10
4. White population -----	33-12
5. White males -----	33-14
6. White females -----	33-16
7. Population other than white -----	33-18
8. Males other than white -----	33-20
9. Females other than white -----	33-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00070—out of every 1,000 reaching their 21st birthday, 0.70 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,268 will complete the first year of life and enter the second, 97,365 will reach age 21, and 59,725 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,732 will die in the first year of life, 69 in the 22d year, and 2,780 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,330. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,330 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,360,464 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,415,275.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,330 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,365 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,360,464) in column 6 is the total number of years lived after attaining age 21 by the 97,365 reaching that age. This number of years divided by the number of persons (5,360,464 divided by 97,365) gives 55.06 as the average remaining lifetime at age 21 for females in this State.

NORTH CAROLINA

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 64.94 years for total males and 73.78 for total females. This State ranks 44th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	34-6
2. Males -----	34-8
3. Females -----	34-10
4. White population -----	34-12
5. White males -----	34-14
6. White females -----	34-16
7. Population other than white -----	34-18
8. Males other than white -----	34-20
9. Females other than white -----	34-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00074—out of every 1,000 reaching their 21st birthday, 0.74 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,905 will complete the first year of life and enter the second, 96,814 will reach age 21, and 58,992 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,095 will die in the first year of life, 72 in the 22d year, and 2,644 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,778. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,778 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,332,573 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,377,564.

Column 7—Average remaining lifetime (e'_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,778 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,814 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,332,573) in column 6 is the total number of years lived after attaining age 21 by the 96,814 reaching that age. This number of years divided by the number of persons (5,332,573 divided by 96,814) gives 55.08 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NORTH CAROLINA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

NORTH DAKOTA

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 69.23 years for total males and 77.01 for total females. This State ranks 4th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	35-8
2. Males -----	35-10
3. Females-----	35-12
4. White population-----	35-14
5. White males -----	35-16
6. White females-----	35-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00064—out of every 1,000 reaching their 21st birthday, 0.64 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,587 will complete the first year of life and enter the second, 97,819 will reach age 21, and 67,873 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,413 will die in the first year of life, 62 in the 22d year, and 2,525 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,787. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,787 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,637,828 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,700,623.

Column 7—Average remaining lifetime (e'_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,787 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,819 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,637,828) in column 6 is the total number of years lived after attaining age 21 by the 97,819 reaching that age. This number of years divided by the number of persons (5,637,828 divided by 97,819) gives 57.64 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NORTH DAKOTA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.25 years for total males and 74.55 for total females. This State ranks 25th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	36-6
2. Males -----	36-8
3. Females-----	36-10
4. White population-----	36-12
5. White males -----	36-14
6. White females-----	36-16
7. Population other than white -----	36-18
8. Males other than white -----	36-20
9. Females other than white-----	36-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00065—out of every 1,000 reaching their 21st birthday, 0.65 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,383 will complete the first year of life and enter the second, 97,456 will reach age 21, and 60,260 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,617 will die in the first year of life, 64 in the 22d year, and 2,756 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,424. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,424 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,397,723 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,454,602.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,424 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,456 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,397,723) in column 6 is the total number of years lived after attaining age 21 by the 97,456 reaching that age. This number of years divided by the number of persons (5,397,723 divided by 97,456) gives 55.39 as the average remaining lifetime at age 21 for females in this State.

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.40 years for total males and 75.70 for total females. This State ranks 19th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	37-6
2. Males -----	37-8
3. Females -----	37-10
4. White population -----	37-12
5. White males -----	37-14
6. White females -----	37-16
7. Population other than white -----	37-18
8. Males other than white -----	37-20
9. Females other than white -----	37-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00082—out of every 1,000 reaching their 21st birthday, 0.82 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,293 will complete the first year of life and enter the second, 97,219 will reach age 21, and 64,789 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,707 will die in the first year of life, 80 in the 22d year, and 2,490 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,179. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,179 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,516,974 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,570,479.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,179 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,219 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,516,974) in column 6 is the total number of years lived after attaining age 21 by the 97,219 reaching that age. This number of years divided by the number of persons (5,516,974 divided by 97,219) gives 56.75 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: OKLAHOMA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.43 years for total males and 76.20 for total females. This State ranks 10th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population-----	38-8
2. Males-----	38-10
3. Females-----	38-12
4. White population-----	38-14
5. White males-----	38-16
6. White females-----	38-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00079—out of every 1,000 reaching their 21st birthday, 0.79 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,530 will complete the first year of life and enter the second, 97,507 will reach age 21, and 65,271 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,470 will die in the first year of life, 77 in the 22d year, and 2,472 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,468. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,468 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,560,299 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,619,662.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,468 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,507 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,560,299) in column 6 is the total number of years lived after attaining age 21 by the 97,507 reaching that age. This number of years divided by the number of persons (5,560,299 divided by 97,507) gives 57.02 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: OREGON, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.90 years for total males and 74.06 for total females. This State ranks 33d among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population-----	39-6
2. Males-----	39-8
3. Females-----	39-10
4. White population-----	39-12
5. White males-----	39-14
6. White females-----	39-16
7. Population other than white-----	39-18
8. Males other than white-----	39-20
9. Females other than white-----	39-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00061—out of every 1,000 reaching their 21st birthday, 0.61 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,245 will complete the first year of life and enter the second, 97,386 will reach age 21, and 58,453 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,755 will die in the first year of life, 59 in the 22d year, and 2,870 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,356. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,356 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,351,414 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,405,635.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,356 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,386 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,351,414) in column 6 is the total number of years lived after attaining age 21 by the 97,386 reaching that age. This number of years divided by the number of persons (5,351,414 divided by 97,386) gives 54.95 as the average remaining lifetime at age 21 for females in this State.

RHODE ISLAND

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.31 years for total males and 75.48 for total females. This State ranks 13th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	40-8
2. Males -----	40-10
3. Females -----	40-12
4. White population -----	40-14
5. White males -----	40-16
6. White females -----	40-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00045—out of every 1,000 reaching their 21st birthday, 0.45 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,402 will complete the first year of life and enter the second, 97,662 will reach age 21, and 62,824 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,598 will die in the first year of life, 43 in the 22d year, and 2,872 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,640. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,640 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,489,623 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,548,294.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,640 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,662 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,489,623) in column 6 is the total number of years lived after attaining age 21 by the 97,662 reaching that age. This number of years divided by the number of persons (5,489,623 divided by 97,662) gives 56.21 as the average remaining lifetime at age 21 for females in this State.

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 63.85 years for total males and 72.29 for total females. This State ranks 50th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	41-6
2. Males -----	41-8
3. Females -----	41-10
4. White population -----	41-12
5. White males -----	41-14
6. White females -----	41-16
7. Population other than white -----	41-18
8. Males other than white -----	41-20
9. Females other than white -----	41-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00082—out of every 1,000 reaching their 21st birthday, 0.82 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,983 will complete the first year of life and enter the second, 96,750 will reach age 21, and 53,932 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,017 will die in the first year of life, 79 in the 22d year, and 2,522 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,710. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,710 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,184,408 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,228,940.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,710 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,750 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,184,408) in column 6 is the total number of years lived after attaining age 21 by the 96,750 reaching that age. This number of years divided by the number of persons (5,184,408 divided by 96,750) gives 53.59 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: SOUTH CAROLINA, 1969-71

SOUTH DAKOTA

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.49 years for total males and 76.19 for total females. This State ranks 11th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	42-8
2. Males -----	42-10
3. Females -----	42-12
4. White population -----	42-14
5. White males -----	42-16
6. White females -----	42-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00099—out of every 1,000 reaching their 21st birthday, 0.99 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,278 will complete the first year of life and enter the second, 97,162 will reach age 21, and 66,601 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,722 will die in the first year of life, 96 in the 22d year, and 2,247 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,114. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,114 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,566,129 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,619,154.

Column 7—Average remaining lifetime (e_x^0)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,114 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,162 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,566,129) in column 6 is the total number of years lived after attaining age 21 by the 97,162 reaching that age. This number of years divided by the number of persons (5,566,129 divided by 97,162) gives 57.29 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: SOUTH DAKOTA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.15 years for total males and 74.26 for total females. This State ranks 38th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	43-6
2. Males -----	43-8
3. Females-----	43-10
4. White population-----	43-12
5. White males -----	43-14
6. White females-----	43-16
7. Population other than white -----	43-18
8. Males other than white -----	43-20
9. Females other than white-----	43-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00079—out of every 1,000 reaching their 21st birthday, 0.79 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,135 will complete the first year of life and enter the second, 97,074 will reach age 21, and 60,510 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,865 will die in the first year of life, 77 in the 22d year, and 2,690 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,036. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,036 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,375,514 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,425,888.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,036 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,074 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,375,514) in column 6 is the total number of years lived after attaining age 21 by the 97,074 reaching that age. This number of years divided by the number of persons (5,375,514 divided by 97,074) gives 55.38 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: TENNESSEE, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.05 years for total males and 74.99 for total females. This State ranks 23d among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	44-6
2. Males -----	44-8
3. Females -----	44-10
4. White population -----	44-12
5. White males -----	44-14
6. White females -----	44-16
7. Population other than white -----	44-18
8. Males other than white -----	44-20
9. Females other than white -----	44-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

50	South Carolina-----	67.96	63.85	72.29	70.32	66.11	74.82	62.64	58.33	67.01
51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00080—out of every 1,000 reaching their 21st birthday, 0.80 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,174 will complete the first year of life and enter the second, 97,096 will reach age 21, and 62,501 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,826 will die in the first year of life, 78 in the 22d year, and 2,503 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,057. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,057 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,447,950 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,498,814.

Column 7—Average remaining lifetime (e'_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,057 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,096 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,447,950) in column 6 is the total number of years lived after attaining age 21 by the 97,096 reaching that age. This number of years divided by the number of persons (5,447,950 divided by 97,096) gives 56.11 as the average remaining lifetime at age 21 for females in this State.

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 69.49 years for total males and 76.55 for total females. This State ranks 3d among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	45-8
2. Males -----	45-10
3. Females -----	45-12
4. White population -----	45-14
5. White males -----	45-16
6. White females -----	45-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00074—out of every 1,000 reaching their 21st birthday, 0.74 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,765 will complete the first year of life and enter the second, 97,739 will reach age 21, and 66,237 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,235 will die in the first year of life, 73 in the 22d year, and 2,599 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,702. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,702 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,591,706 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,655,376.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,702 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,739 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,591,706) in column 6 is the total number of years lived after attaining age 21 by the 97,739 reaching that age. This number of years divided by the number of persons (5,591,706 divided by 97,739) gives 57.21 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: UTAH, 1969-71

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life-at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 67.76 years for total males and 75.77 for total females. This State ranks 18th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	46-8
2. Males -----	46-10
3. Females-----	46-12
4. White population-----	46-14
5. White males -----	46-16
6. White females-----	46-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00045—out of every 1,000 reaching their 21st birthday, 0.45 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,561 will complete the first year of life and enter the second, 97,802 will reach age 21, and 63,382 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,439 will die in the first year of life, 44 in the 22d year, and 2,696 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,780. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,780 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,515,408 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,576,775.

Column 7—Average remaining lifetime (e'_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,780 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,802 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,515,408) in column 6 is the total number of years lived after attaining age 21 by the 97,802 reaching that age. This number of years divided by the number of persons (5,515,408 divided by 97,802) gives 56.39 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: VERMONT, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.26 years for total males and 74.17 for total females. This State ranks 40th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	47-6
2. Males -----	47-8
3. Females-----	47-10
4. White population-----	47-12
5. White males -----	47-14
6. White females-----	47-16
7. Population other than white -----	47-18
8. Males other than white -----	47-20
9. Females other than white-----	47-22

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00065—out of every 1,000 reaching their 21st birthday, 0.65 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,125 will complete the first year of life and enter the second, 97,157 will reach age 21, and 59,195 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,875 will die in the first year of life, 63 in the 22d year, and 2,653 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,126. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,126 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,366,088 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,417,263.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,126 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,157 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,366,088) in column 6 is the total number of years lived after attaining age 21 by the 97,157 reaching that age. This number of years divided by the number of persons (5,366,088 divided by 97,157) gives 55.23 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: VIRGINIA, 1969-71

AGE IN YEARS PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED (1)	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAIN- ING LIFETIME
	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE
x to $x+1$	q_x	l_x	d_x	L_x	T_x	e_x

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 68.07 years for total males and 75.78 for total females. This State ranks 16th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	48-8
2. Males -----	48-10
3. Females -----	48-12
4. White population -----	48-14
5. White males -----	48-16
6. White females -----	48-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00064—out of every 1,000 reaching their 21st birthday, 0.64 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,470 will complete the first year of life and enter the second, 97,587 will reach age 21, and 63,910 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,530 will die in the first year of life, 63 in the 22d year, and 2,550 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,556. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,556 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,519,110 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,577,836.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,556 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,587 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,519,110) in column 6 is the total number of years lived after attaining age 21 by the 97,587 reaching that age. This number of years divided by the number of persons (5,519,110 divided by 97,587) gives 56.56 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WASHINGTON, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 65.56 years for total males and 73.74 for total females. This State ranks 42d among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population-----	49-8
2. Males-----	49-10
3. Females-----	49-12
4. White population-----	49-14
5. White males-----	49-16
6. White females-----	49-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00066—out of every 1,000 reaching their 21st birthday, 0.66 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,086 will complete the first year of life and enter the second, 97,048 will reach age 21, and 58,693 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,914 will die in the first year of life, 64 in the 22d year, and 2,726 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,016. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,016 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,325,628 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,374,405.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,016 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,048 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,325,628) in column 6 is the total number of years lived after attaining age 21 by the 97,048 reaching that age. This number of years divided by the number of persons (5,325,628 divided by 97,048) gives 54.88 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WEST VIRGINIA, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 69.15 years for total males and 76.04 for total females. This State ranks 8th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population -----	50-8
2. Males -----	50-10
3. Females -----	50-12
4. White population -----	50-14
5. White males -----	50-16
6. White females -----	50-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00065—out of every 1,000 reaching their 21st birthday, 0.65 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 98,530 will complete the first year of life and enter the second, 97,641 will reach age 21, and 64,791 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 1,470 will die in the first year of life, 63 in the 22d year, and 2,660 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 97,610. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 97,610 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,543,603 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,604,039.

Column 7—Average remaining lifetime (e_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 97,610 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 97,641 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,543,603) in column 6 is the total number of years lived after attaining age 21 by the 97,641 reaching that age. This number of years divided by the number of persons (5,543,603 divided by 97,641) gives 56.78 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WISCONSIN, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMBER LIVING AT BEGINNING OF YEAR OF AGE	NUMBER DYING DURING YEAR OF AGE	IN YEAR OF AGE	IN THIS YEAR OF AGE AND ALL SUBSEQUENT YEARS	AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF YEAR OF AGE

WYOMING

STATE LIFE TABLES: 1969-71

T. N. E. Greville, Ph.D., *Division of Vital Statistics*

This report contains the 1969-71 detailed life tables for this State. Separate life tables have been calculated for each State for white persons and for the population other than white separately by sex and for both sexes combined and also for the total population and for total males and total females. However, the life tables for any color grouping (white or other than white) in any State have not been published when the total number of deaths at all ages for either males or females is less than 1,600.

The tables are based on the 1970 Census of Population and on the average annual number of resident deaths during the 3-year period 1969-71. In deriving life-table values at ages under 2, reported births for the years 1967-71 have also been used. Mortality rates ("proportions dying") at ages 95 and over are based on the experience of the Medicare program of the Social Security Administration. These are differentiated by color and sex but not by State. Values at ages 85-94 have also been adjusted to provide a smooth transition between the mortality rates based on the census and registered deaths and those derived from the Medicare program. Therefore the figures at ages 85 and above may fail to reflect adequately variation in mortality among the States. Such variation, however, is in general smaller than differences associated with color and sex. The population and death statistics at ages under 85 are known to be subject to certain errors, but these were not considered to be serious enough to require adjustment prior to the calculation of the life tables. However, in some instances, fluctuations due to the small volume of data produced anomalous life-table values, which

were eliminated by minor redistribution of deaths by age.

A report in Volume I of this series contains a complete description of the methods and formulas by which the national and State life tables were prepared, and an explanation of the columns of the life table precedes the tables in this State report.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject throughout its existence to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 3 is a life table for females; it shows the progress of a cohort starting with 100,000 live births and subject during its passage through successive years of age to the average annual mortality rates observed among females in this State in the 3-year period 1969-71.

Column 7 of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1969-71 life tables for this State, the expectation of life at birth is 66.19 years for total males and 75.19 for total females. This State ranks 35th among the 50 States and the District of Columbia in the expectation of life at birth for the total population.

The table on the following page shows the average lifetime (or expectation of life at birth) by color and sex for the population of the United States, each State, and the District of Columbia.

Table	Page
1. Total population-----	51-8
2. Males-----	51-10
3. Females-----	51-12
4. White population-----	51-14
5. White males-----	51-16
6. White females-----	51-18

AVERAGE LIFETIME IN YEARS BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1969-71

(States are ranked according to the average lifetime for the total population)

Rank	Area	Total			White			All other		
		Both sexes	Male	Female	Both sexes	Male	Female	Both sexes	Male	Female
1	Hawaii-----	73.60	71.02	76.79	(1)	(1)	(1)	73.67	71.08	76.93
2	Minnesota-----	72.96	69.38	76.80	73.04	69.46	76.87	(1)	(1)	(1)
3	Utah-----	72.90	69.49	76.55	72.95	69.54	76.60	(1)	(1)	(1)

51	District of Columbia--	65.71	60.92	70.52	70.64	66.08	74.76	63.55	58.96	68.34

¹ Not computed because fewer than 1,600 female or male deaths of this color were registered in the 3-year period 1969-71.

EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

Column 1—Year of age (x to $x+1$)—The year of age shown in column 1 is the interval of 1 year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

Column 2—Proportion dying (q_x)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday on the basis of the mortality rates of 1969-71 for females in this State. For example, for females in the year of age 21-22, the proportion dying is .00092—out of every 1,000 reaching their 21st birthday, 0.92 will die before reaching their 22d birthday.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the birthday marking the beginning of the indicated year of age. Thus out of 100,000 babies born alive in the cohort of table 3, 97,844 will complete the first year of life and enter the second, 96,598 will reach age 21, and 64,529 will live to age 75.

Column 4—Number dying (d_x)—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 3, 2,156 will die in the first year of life, 88 in the 22d year, and 2,504 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (L_x and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population

supported by 100,000 annual births, column 3 shows the number of persons who each year will reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who will die each year in that year of age. Column 5, L_x , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 3 for the year of age 21-22 is 96,554. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,544 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of females described in the preceding paragraph, column 6 shows that there would be at any given moment 5,476,930 persons who had reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of females) would be 7,519,495.

Column 7—Average remaining lifetime (e_x^o)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 96,554 for females in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,598 (column 3) who reached the 21st birthday out of the original cohort of 100,000, and the corresponding figure (5,476,930) in column 6 is the total number of years lived after attaining age 21 by the 96,598 reaching that age. This number of years divided by the number of persons (5,476,930 divided by 96,598) gives 56.70 as the average remaining lifetime at age 21 for females in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WYOMING, 1969-71

AGE IN YEARS	PROPORTION DYING	OF 100,000 BORN ALIVE		STATIONARY POPULATION		AVERAGE REMAINING LIFETIME
		PERIOD OF LIFE BETWEEN TWO EXACT AGES STATED	PROPORTION OF PERSONS ALIVE AT BEGINNING OF YEAR OF AGE DYING DURING YEAR	NUMREP LIVING AT BEGINNING OF YEAR OF AGE	NUMREP DYING DURING YEAR OF AGE
