Preparation of the life tables

Robert J. Armstrong of the Division of Vital Statistics, National Center for Health Statistics, developed the content of the life tables and the methodology to produce them. He was also responsible for coordinating all the activities of the Social Security Administration, the U.S. Bureau of the Census, and the various components of the National Center for Health Statistics that contributed to the production of these life tables.

Nonie Atkinson of the Office of Research and Methodology was responsible for the overall computer systems analysis and design, and played a major role in writing the programs to produce the life tables and their variances.

Anne K. Stratton of the Computer Applications Staff of the Division of Vital Statistics coordinated all data processing and developed computer processes which eased the workload of the actuarial statistician and the Publications Branch. She

also provided major programming support in summarizing data basic to the calculation of the life tables.

John E. Mounts, Ann A. Swain, Arlett R. Brown, and Barbara B. Beals of the Publications Branch, Division of Data Services, provided consultation, publications management, and editorial review. Stephen L. Sloan supervised the production of the cover design, and Linda L. Bean coordinated the printing.

An ad hoc committee provided guidance and many helpful suggestions on the methodology and content of the life tables. This committee was headed by Thomas N. E. Greville of the University of Wisconsin. Other members were Francisco Bayo, Joseph Faber, and John Wilkin of the Office of the Actuary, Social Security Administration; Jacob S. Siegel and Jeffrey Passel of the U.S. Bureau of the Census; and various staff members of the National Center for Health Statistics.

United States Life Tables: 1979–81

Generation and current life tables

The mortality rates for a specific period may be summarized by the life-table method to obtain measures of comparative longevity. There are two types of life tables—the generation or cohort life table and the current or “snapshot” life table. The generation life table provides a “longitudinal” perspective in that it follows the mortality experience of an actual cohort—for example, all persons born in the year 1900—from the moment of birth through consecutive ages in successive years. Based on age-specific mortality rates observed during consecutive years, the generation life table reflects the mortality experience of a cohort from birth until no lives remain in the group.

The better known current life table may, by contrast, be characterized as “cross-sectional.” Unlike the generation life table, the current life table considers a hypothetical cohort and assumes that it is subject throughout its existence to the age-specific mortality rates observed for an actual population during a particular period of relatively short duration (often 1 to 3 years).

Decennial life tables for 1979–81

The life tables in this report are current life tables for the United States based on age-specific mortality rates for the period 1979–81. With the exception of those for ages 95 and over (and to a lesser extent those for ages 85–94), these mortality rates have been calculated from the data of the 1980 Census of Population and deaths occurring in the United States in the 3 years 1979–81. In deriving life-table values at ages under 2, reported births for each of the years 1977 to 1981 have also been used. Mortality rates at ages 95 and over, where the data from the census and from registered deaths are scanty and unreliable, are based on the experience of the Medicare program. They were provided by the Office of the Actuary of the Social Security Administration, and thanks are due especially to Francisco Bayo, Deputy Chief Actuary, and Alice Wade, Actuary.

Tables 1–12 are life tables for the white population, the population other than white, and the black population, separately by sex and for both sexes combined, and also for the total population and for total males and total females.

These tables are the most recent in a series of life tables that have been prepared at 10-year intervals for the death-registration States; the series began with those for 1900–1902. Each of the tables in the series is based on a census of popula-

tion and deaths in a 3-year period containing the census year. These decennial life tables differ in two main respects from the life tables prepared and published annually in *Vital Statistics of the United States*: the annual tables are based on deaths in a single year and, except for census years, on postcensal population estimates rather than directly on the data of a decennial census, and the annual tables are calculated by abbreviated methods.

This report is the first of a series of reports containing life tables for 1979–81 and other information related to the decennial life-table program. Also included in the series will be 51 reports containing life tables for the individual States and the District of Columbia, a methodological report that will describe in detail the methods of construction of the national and State life tables, an analytical report dealing with trends and interpretations related to life expectancy and survivorship, and a report on life tables analyzed by major groups of causes of death.

Preliminary adjustment of data

Although the 1969–71 decennial life tables for the United States did not require any smoothing of the underlying data, some minor adjustments in the numbers of deaths by age were needed in all race-sex groups between the ages of 10 and 24.

Certain other minor adjustments have also been incorporated. In accordance with standard practice, deaths for which age was not stated have been allocated proportionately among the various age groups. The population data used differ from the official data published by the U.S. Bureau of the Census. The 1980 census counts were modified by race, keeping the age-sex totals fixed. This modification resulted in about 6.3 million persons and 188,000 persons being added to the white and black populations, respectively.¹ Thanks are due to Jeffrey Passel and Louisa Miller of the U.S. Bureau of the Census for furnishing magnetic tapes containing these modified-race populations. These are the population data used in the preparation of the life tables contained in this report.

¹U.S. Bureau of the Census: Estimates of the population of the United States, by age, sex, and race: 1980 to 1983. *Current Population Reports*, Series P-25, No. 949. Washington. U.S. Government Printing Office, May 1984. The types of errors mentioned are described on p. 6.

Measures of comparative longevity

The life table provides a convenient tool for comparing the longevity of different populations or of different subdivisions of a population. The customary measure of longevity is the average duration of life, also called the expectation of life at birth. This is the average number of years lived by the members of the life-table cohort. Based on the mortality experience of 1979–81, the expectation of life at birth is 70.82 years for white males, 78.22 for white females, 64.10 for black males, and 72.88 for black females. These values reflect the higher mortality of males over females and of black over white persons (except at older ages starting at about 85). Expectation of life at birth for white females is 7.40 years longer than for white males, and the corresponding excess for black females over black males is 8.78 years. It appears that sex has a greater influence on this statistic than race, since the expectation of life at birth for black females exceeds that for white males by 2.06 years.

Expectation of life at birth (\bar{e}_0) is strongly affected by the relatively large number of deaths occurring during the first year of life. In comparing the longevity of different populations, it may be desirable to consider also expectation of life at age 1 (\bar{e}_1), since this measure is not affected by the infant mortality rate. Indeed, in the 1969–71 life tables \bar{e}_1 was greater than \bar{e}_0 in all population groups. For the 1979–81 life tables this relationship holds only for the population other than white and the black population (tables 7–12). The 1979–81 values of \bar{e}_1 are 70.70 years for white males, 77.98 for white females, 64.60 for black males, and 73.31 for black females. The increase in expectation of life at age 1 over age 0 is moderate for black males and females (.50 and .43 years, respectively), but there is actually a drop for white males and females (−.12 and −.24 years, respectively); this reflects the higher infant mortality of the black population.

It may be of interest for certain purposes to examine average remaining lifetime at other ages. For example, ages 21, 62, and 65 may be regarded as representing, respectively, the traditional age for the attainment of adulthood, the minimum retirement age prescribed by the Social Security Act, and the normal retirement age. The 1979–81 values of expectation of life at age 21 are 51.54 for white males, 58.47 for white females, 45.59 for black males, and 53.94 for black females. Corresponding values for age 62 are 16.19, 20.86, 14.82, and 19.07 years; and for age 65 they are 14.26, 18.55, 13.29, and 17.13 years.

The concept of expectation of life is misleading if it is taken to imply the notion of forecasting. It is important to understand that expectation of life values forecast average remaining lifetime only for the hypothetical cohort of the life table. Comparable forecasts for any actual population would have to take into account future mortality trends as well as current mortality rates.

Another possible yardstick for comparing the longevity of different populations is the median length of life, or probable lifetime, which is the age at which exactly half the original members of the life-table cohort have died. When the cohort starts with 100,000 births, this would be the age at which there are just 50,000 survivors. Easily calculated from the l_x values

in the life tables, the median length of life at birth, based on the mortality rates of 1979–81, is 74.21 years for white males, 81.81 for white females, 67.37 for black males, and 76.62 for black females. In calculating the median length of life, it is assumed that deaths are evenly distributed within the age interval containing the median age.

A comparison of the probable lifetime with the expectation of life at birth shows that the former exceeds the latter for each population subgroup. Thus the median length of life at birth for 1979–81 is 3.39 years more than the expectation of life for white males; for white females, 3.59 years; for black males, 3.27 years; and for black females, 3.74 years. These differences are due to the asymmetrical, or skewed, character of the statistical distribution of deaths in the life-table cohort; the relatively large number of deaths in the first year of life plays a major role in producing this asymmetry.

Still another measure of comparative longevity is the number (or percentage) of persons in the original cohort surviving to a specified age. Such data are supplied by the l_x column of the life tables. Thus on the basis of 1979–81 mortality, the percentage of white males surviving to age 1 is 98.8; of white females, 99.0; of black males, 97.7; and of black females, 98.1. At age 21 the corresponding percentages are 97.4, 98.3, 95.9, and 97.1; and at age 65 they are 72.4, 84.8, 55.1, and 73.3.

These life tables are based on a complete count of resident deaths in the United States during the 3 years of 1979, 1980, and 1981. As such, they are not subject to sampling error. However, even complete counts may be considered as one of a large series of possible results that could have arisen under the same circumstances. This type of variation is known as random error. The reader should remember that the standard errors shown in this report reflect only this random error. Other errors, such as misreporting age on death certificates or in the census, are not reflected in them.

Standard errors of the probability of dying and of life expectancy are being shown with these life tables for the first time. They contain six and three decimal places, respectively, for the probability of dying and the life expectancy and appear in tables 13 and 14. In both cases the standard errors contain one place more than the corresponding variable in the life tables. In computing confidence intervals the limits are rounded to the same number of decimal places as the variable has in the life table.

To obtain a 68-percent confidence interval for the probability of dying at any age take the point estimate from column 2 of the appropriate life table and add and subtract one standard error (from table 13). The 95-percent confidence interval is obtained by adding and subtracting two standard errors. For example, the probability that a 50-year-old white female will die before her 51st birthday is .00376 with a standard error of .000035. Therefore the 68-percent confidence interval is from .00372 to .00380 and the 95-percent confidence interval is from .00369 to .00383. The life expectancy of a 50-year-old white female is 30.96 years with a standard error of .007 years. The 68-percent confidence interval for the life expectancy is therefore from 30.95 to 30.97 years and the 95-percent confidence interval is also from 30.95 to 30.97 years. Both confidence intervals are the same when rounded to two decimals.

Explanation of the columns of the life table (Figures used for illustration are from table 6)

Column 1—Age interval (x to $x + t$)—The age interval shown in column 1 is the interval between two exact ages indicated. For instance, "7–28 days" means the 21-day interval between the exact ages of 7 days and 28 days, and "43–44 years" means the interval of 1 year between the 43d and 44th birthdays. In the life tables in this report the age interval is always 1 year except in the case of subdivisions of the first year of life.

Column 2—Proportion dying (${}_1q_x$)—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated age interval who will die before reaching the end of that age interval (in most instances, the next birthday) on the basis of the mortality rates of 1979–81. For example, for white females in the age interval 7–28 days, the proportion dying is .00111—out of every 1,000 white female babies surviving 7 days after birth, 1.11 will die before reaching the age of 28 days. Similarly, for white females in the age interval 43–44 years, the proportion dying is .00192—out of every 1,000 white females reaching their 43d birthday, 1.92 will die before reaching their 44th birthday. When the age interval is 1 year, the symbol q_x (instead of ${}_1q_x$) is generally used for the proportion dying.

Column 3—Number surviving (l_x)—This column shows the number of persons, starting with a cohort of 100,000 live births, who will survive to the exact age marking the beginning of the indicated age interval. Thus out of 100,000 white female babies born alive, 99,449 will survive 7 days, 99,035 will complete the first year of life and enter the second, 98,319 will reach age 21, and 68,712 will live to age 75.

Column 4—Number dying (${}_1d_x$)—This column shows the number dying in each successive age interval out of 100,000 live births. Thus out of 100,000 white females born alive, 110 will die between the ages of 7 and 28 days, 965 will die in the entire first year of life, and 185 will die in the year between their 43d and 44th birthdays. Evidently each figure in column 4 is the difference between two successive figures in column 3. When the age interval is 1 year, the symbol d_x (instead of ${}_1d_x$) is generally used for the number dying.

Columns 5 and 6—Stationary population ($,L_x$ and T_x)—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born every year, and that the proportions dying in each such group in each age interval throughout the lives of the members are exactly those shown in column 2. If there were no migration and if the births were evenly distributed over the year, the survivors of these births would constitute what is called a stationary population, because in such a population the number of persons living in any given age interval would never change. When an individual left an age interval, whether by death or by growing older and entering the next higher age interval, his place would immediately be taken by someone entering from the next lower age interval. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various age intervals. In such a stationary population supported by 100,000 annual

births, column 3 shows the number of persons who, each year, will reach the exact age that marks the beginning of the age interval indicated in column 1, and column 4 shows the number of persons who will die each year in the indicated age-interval.

Column 5, $,L_x$, shows the number of persons in the stationary population in the indicated age interval. For example, the figure shown for white females in the age interval 7–28 days is 5,719. This means that in a stationary population of white females supported by 100,000 annual births, and with proportions dying in each age interval always in accordance with column 2, a census taken on any date would show 5,719 persons between the exact ages of 7 and 28 days. Similarly, the number of white females in the year of age 43–44 is 96,361. Thus the stationary population described would always contain 96,361 persons between their 43d and 44th birthdays. When the age interval is 1 year, the symbol L_x is generally used instead of $,L_x$.

Column 6, T_x , shows the total number of persons in the stationary population (column 5) in the indicated age interval and all subsequent age intervals. For example, in the stationary population of white females described in the preceding paragraph, column 6 shows that there would be at any given moment a total of 7,820,074 persons who had survived at least 7 days following birth and a total of 3,602,150 persons who had attained age 43. The population at all ages 0 and above (in other words, the total white female population of the stationary community) would be 7,821,984.

Column 7—Average remaining lifetime (\bar{e}_x)—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 of the life tables can also be interpreted in terms of a single life-table cohort without introducing the concept of the stationary population. From this point of view, each figure in column 5 represents the total time in years lived between two indicated exact ages by all those reaching the younger age among the survivors of a cohort of 100,000 live births. Thus the figure of 5,719 for white females in the age interval 7–28 days is the total number of years of life lived between the exact ages of 7 and 28 days by the 99,449 (column 3) who reached the age of exactly 7 days out of 100,000 white females born alive. The corresponding figure (7,820,074) in column 6 is the total number of years lived after attaining the age of 7 days by the 99,449 reaching that exact age. Similarly, the figure 96,361 in column 5 for white females in the year of life 43–44 is the total number of years lived between their 43d and 44th birthdays by the 96,453 (column 3) who reached the 43d birthday out of the original cohort of 100,000, and the corresponding figure (3,602,150) in column 6 is the total number of years lived after attaining age 43 by the 96,453 reaching that age.

This number of years divided by the number of persons (3,602,150 divided by 96,453) gives 37.35 years as the average remaining lifetime at age 43. A similar division of 7,820,074 by 99,449 gives 78.63 years as the average remaining lifetime at the age of 7 days.

Care must be exercised in drawing conclusions from the figures in column 7. Thus in observing that the average remaining lifetime of white persons is greater than that of black persons, one should not conclude that the oldest ages reached by white persons necessarily exceed those attained by the most long-lived black persons. The difference in average length of life

results from the fact that a greater proportion of black people die before reaching old age. For example, the proportion surviving to age 65 is far greater among white than black persons; yet the average length of life remaining at age 65 is nearly the same for both groups.

Detailed tables

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: UNITED STATES, 1979-81

| AGE INTERVAL | PROPORTION DYING | OF 100,000 BORN ALIVE | | STATIONARY POPULATION | | AVERAGE REMAINING LIFETIME |
|---------------------------------|--|--|----------------------------------|-----------------------|--|--|
| PERIOD OF LIFE BETWEEN TWO AGES | PROPORTION OF PERSONS ALIVE AT BEGINNING OF AGE INTERVAL DYING DURING INTERVAL | NUMBER LIVING AT BEGINNING OF AGE INTERVAL | NUMBER DYING DURING AGE INTERVAL | IN THE AGE INTERVAL | IN THIS AND ALL SUBSEQUENT AGE INTERVALS | AVERAGE NUMBER OF YEARS OF LIFE REMAINING AT BEGINNING OF AGE INTERVAL |
| (1) | (2) | (3) | (4) | (5) | (6) | (7) |
| x to $x + t$ | tq_x | l_x | td_x | tL_x | T_x | \bar{e}_x |

U.S. Decennial Life Tables, 1979-81

These 55 reports are published once each 10-year period by the National Center for Health Statistics.

VOLUME I

- Number 1** *United States Life Tables.* This first report contains life tables by single years of age from birth to age 110 for the United States. Tables are included for the total population, the white population, the population other than white, and the black population. Within these large populations are tables showing the race-sex categories of male, female, and both sexes combined. Standard error tables for the probability of dying and of the average remaining lifetime are included for the first time in this series.
- Number 2** *United States Life Tables Eliminating Certain Causes of Death.* This report provides life tables analyzed by major groups of causes of death.
- Number 3** *Methodology of the National and State Life Tables.* This report describes in detail the methods of construction of the national and State life tables.
- Number 4** *Some Trends and Comparisons of United States Life Table Data: 1900-1981.* This report deals with trends and interpretations related to life expectancy and survivorship.

VOLUME II

- Numbers 1 through 51** *Alabama through Wyoming, State Life Tables.* Each of these 51 reports contains life tables for a particular State and a table which ranks each State in the order of life expectancy. All States have tables for the total population and the white population by sex. In addition 35 States have tables for the other than white population and 31 have tables for the black population. Standard error tables for the probability of dying and of the average remaining lifetime are included for the first time in this series.
