VITAL STATISTICS OF THE UNITED STATES, 1970

VOLUME II — MORTALITY

A brief summary of the contents for each section is listed below for the convenience of the reader. A complete contents page is at the beginning of each section and is identified by a narrow black edge which can be located easily by fanning the pages. Each section is paged independently, using the section number as the identifying prefix.

PART A

Section 1. General Mortality

Summary tables containing crude, age-specific, and age-adjusted death rates; death rates by cause; maternal mortality; and deaths for the 50 largest standard metropolitan statistical areas. Detailed tabulations of deaths by cause for the United States and each State. Data shown by age, sex, color and race, cause of death, and month.

Section 2. Infant Mortality

Tabulations of infant deaths and infant mortality rates by age, color, sex, and cause of death, and by State and the 50 largest standard metropolitan statistical areas. Additional frequency tables by month of death and by population-size groups in metropolitan and nonmetropolitan counties.

Section 3. Fetal Mortality

Tabulations of numbers of deaths and ratios by color, age of mother, legitimacy status, geographic areas, and population-size groups; and fetal-death rates by plurality and sex. Numbers of deaths by additional categories—month, birth order, attendant, period of gestation, and birth weight.

Section 4. Accident Mortality

Deaths from motor vehicle accidents by type of vehicle and from nontransport accidents by place of accidents and by person injured. Data shown by cause of death, age, color, and sex for the United States and by color and sex for each State. Deaths from accidental poisoning by age, color, and sex.

Section 5. Life Tables

Abridged life tables and interpolated values of the l_x and e_x^0 by single years of age for the national population by color and sex.

Section 6. Technical Appendix

Text discussion of factors affecting the collection, classification, and interpretation of the mortality statistics published in Volume II. Includes population tables for computing vital rates.

PART B

Section 7. Geographic Detail for Mortality

Total number of deaths, deaths from selected causes, infant deaths, neonatal deaths, fetal deaths, and selected rates and ratios. Tabulations shown by each State and county, specified urban places, metropolitan and nonmetropolitan counties, population-size groups, and standard metropolitan statistical areas.

Section 8. Guam, Puerto Rico, and Virgin Islands (U.S.)

Trend of the crude death rate. Frequency tabulations for most of the characteristics shown in other sections of Volume II.

Complete contents pages for Sections 7 and 8 are on pages 7-1 and 8-1. Sections 1 through 6 are in Part A of Volume II of *Vital Statistics of the United States, 1970*. Section 6, the Technical Appendix, discusses the factors affecting the collection, classification, and interpretation of the mortality statistics.

SECTION 1 · GENERAL MORTALITY

Table 1-10. Death Rates for Geographic Divisions by Place of Occurrence: United States, 1900-1970

Prior to 1933, data for death registration States only. Rates per 1,000 population in each area. Average rates computed from 5-year totals of deaths occurring in the area and corresponding population. Rates are shown for each division from the period when the division as a whole became part of the death-registration area]

¹Period of gestation reported in months allocated to gestation intervals in weeks as shown in the Technical Appendix.²Further specifies that certificates for fetal deaths of less than 20 weeks of gestation may be filed although registration is not mandatory.³For areas which report fetal deaths at all periods of gestation, those at gestations of under 16 weeks are distributed as follows:

	Total	Under 4 weeks	4-7 weeks	8-11 weeks	12-15 weeks
Arkansas-----	89	-	29	26	34
Colorado-----	1,587	33	162	707	685

Vermont-----	185	1	9	91	84
Virginia-----	4,724	45	1,075	2,421	1,185

⁴Further stipulates that "when the length of gestation is not determinable the following criteria may be used: A. weight of 400 grams or more; B. crown-heel length of 28 centimeters or more. If both of the above criteria are met the fetus should be registered as a fetal death."⁵Further specifies that "if the gestation period is unknown but the fetus weighs 400 grams or more, a fetal death certificate must be filed."⁶Further specifies "or total length of 10 inches."

¹Excludes fetal deaths among nonresidents of the United States.

²Figures for 1966 exclude approximately 300 fetal deaths recorded in Massachusetts, and figures for 1967 exclude approximately 100 fetal deaths recorded in this State. These fetal deaths were primarily to residents of Massachusetts. See Technical Appendix.

³This State requires reporting of all fetal deaths regardless of period of gestation. Prior to 1963 fetal deaths for which gestation was not stated are included in computing the ratios in this table, the ratios for this State may be overstated as a result of inclusion of some early fetal deaths from the "not stated" group.

Explanation of the Columns of the Life Table

Column 1—Age interval (x to $x+n$).—The age interval shown in column 1 is the interval between the two exact ages indicated. For instance, "20-25" means the 5-year interval between the 20th birthday and the 25th.

Column 2—Proportion dying (${}_nq_x$).—This column shows the proportion of the cohort who are alive at the beginning of an indicated age interval and who will die before reaching the end of that age interval. For example, for males in the age interval 20-25, the proportion dying is 0,0112—out of every 1,000 males alive and exactly 20 years old at the beginning of the period, 11 will die before reaching their 25th birthday. In other words, the ${}_nq_x$ values represent *probabilities* that persons who are alive at the beginning of a specific age interval will die before reaching the beginning of the next age interval. The "proportion dying" column forms the basis of the life table; the life table is so constructed that all other columns are derived from it.

Column 3—Number surviving (l_x).—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the exact age marking the beginning of each age interval. The l_x values are computed from the ${}_nq_x$ values, which are successively applied to the remainder of the original 100,000 persons still alive at the beginning of each age interval. Thus out of 100,000 male babies born alive, 97,745 will complete the first year of life and enter the second; 97,298 will begin the sixth year; 96,128 will reach age 20; and 13,256 will live to age 85.

Column 4—Number dying (${}_nd_x$).—This column shows the number dying in each successive age interval out of 100,000 live births. Out of 100,000 males born alive, 2,255 die in the first year of life, 364 in the succeeding 4 years, 1,079 in the 5-year period between exact ages 20 and 25, and 13,256 die after reaching age 85. Each figure in column 4 is the difference between two successive figures in column 3.

Columns 5 and 6—Stationary population (${}_nL_x$ and T_x).—Suppose that a group of 100,000 individuals like that assumed in columns 3 and 4 is born every year and that the proportions dying in each such group in each age interval throughout the lives of the members are exactly those shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would make up what is called a stationary population—stationary because in such a population the number of persons living in any given age group would never change. When an individual left the group, either by death or by growing older and entering the next higher age group, his place would immediately be taken by someone entering from the next lower age group. Thus a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various age groups. In such a stationary population supported by 100,000 annual births, column 3 shows the number of persons who, each year,

reach the birthday which marks the beginning of the age interval indicated in column 1, and column 4 shows the number of persons who die each year in the indicated age interval.

Column 5 shows the number of persons in the stationary population in the indicated age interval. For example, the figure given for males in the age interval 20-25 is 477,977. This means that in a stationary population of males supported by 100,000 annual births and with proportions dying in each age group always in accordance with column 2, a census taken on any date would show 477,977 persons between exact ages 20 and 25.

Column 6 shows the total number of persons in the stationary population (column 5) in the indicated age interval and all subsequent age intervals. For example, in the stationary population of males referred to in the last illustration, column 6 shows that there would be at any given moment a total of 4,769,722 persons who have passed their 20th birthday. The population at all ages 0 and above (in other words, the total population of the stationary community) would be 6,711,932.

Column 7—Average remaining lifetime (e'_x).—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age on the basis of a given set of age-specific rates of dying. In order to arrive at this value, it is first necessary to observe that the figures in column 5 of the life table can also be interpreted in terms of a single life table cohort without introducing the concept of the stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus the figure 477,977 for males in the age interval 20-25 is the total number of years lived between the 20th and 25th birthdays by the 96,128 (column 3) who reached the 20th birthday out of 100,000 males born alive. The corresponding figure (4,769,722) in column 6 is the total number of years lived after attaining age 20 by the 96,128 reaching that age. This number of years divided by the number of persons (4,769,722 divided by 96,128) gives 49.6 years as the average remaining lifetime of males at age 20.

Care must be exercised in drawing conclusions from the figures in column 7. Thus in observing that the average remaining lifetime of white persons is greater than for those in the all other category, one should not conclude that the oldest ages reached by white persons necessarily exceed those attained by the most long-lived of the all other group. The difference in the average length of life results from the fact that a greater proportion of all other persons die before reaching old age. For example, the number surviving to age 65 out of 100,000 born alive is far greater among white persons than among all other persons; yet the average length of life remaining at age 65 is nearly the same for both groups.

SECTION 5 - LIFE TABLES

Table 5-4. Life Table Values by Color and Sex: Death-Registration States, 1900-1902 to 1919-21, and United States, 1929-31 to 1970

[Alaska and Hawaii included for 1959 and 1960. For decennial periods prior to 1929-31, data are for groups of registration States as follows: 1900-1902 and 1909-11, 10 States and the District of Columbia; 1919-21, 34 States and the District of Columbia. For 1900-1902 to 1929-31, figures for "all other, male" and "all other, female" cover only Negroes. However, in no case did the Negro population comprise less than 95 percent of the corresponding "all other" population]

SECTION 6. TECHNICAL APPENDIX

SOURCES OF DATA

Death and fetal-death statistics

Death and fetal-death statistics are based on information obtained from copies of the original certificates received from the registration offices of all States, certain cities, the District of Columbia, Puerto Rico, the Virgin Islands, and Guam. The statistical information on these records is edited, coded onto magnetic tape for computer processing, and tabulated in the National Center for Health Statistics (NCHS). Fetal deaths are classified and tabulated separately from all other deaths.

In the statistical tabulations, *United States* refers only to the aggregate of the 50 States and the District of Columbia. Alaska has been included in the United States tabulations since 1959 and Hawaii since 1960. Tabulations for Puerto Rico and the Virgin Islands were shown in the annual volumes until 1966, but were not presented in the volumes from 1967 to 1969. Tabulations for these areas were reinstated in 1970, while those for Guam were included for the first time.

Standard certificates

Standard certificates of death and fetal death, issued by the Public Health Service, have served for many years as the principal means of attaining uniformity in the content of the documents used to collect information on these events. They have been modified in each State to the extent necessitated by the particular needs of the State or by special provisions of the State vital statistics law. However, the certificates of most States conform closely in content and arrangement to the standard certificates.

The first issue of the Standard Certificate of Death appeared shortly before the formation of the registration area. Since then it has been revised periodically by the Division of Vital Statistics through consultation with State health officers and registrars; Federal agencies concerned with vital statistics; national, State, and county medical societies; and others working in the fields of public health, social welfare, demography, and insurance. This revision procedure has assured careful evaluation of each item in terms of its current and future usefulness for registration, identification, legal, medical, and research purposes. New items have been added when necessary, and old items have been modified to ensure better reporting or in some cases have been dropped when their usefulness appeared to be limited.

New revisions of the standard certificates of death and fetal death have been recommended for State use beginning January 1, 1968. These standard certificates are shown in figures 6-A and 6-B. The certificate of death shown in figure 6-A is for use by either a physician or a medical examiner or coroner. Two other forms of the Standard Certificate of Death are available; they are similar to the one shown except that the section on certification is designed for the physician's signature on one while the other is designed for the medical examiner's or coroner's signature.

HISTORY

The first death statistics published by the Federal Government concerned events in 1850 and included the entire United States. These statistics were based on information collected during the decennial census of that year. Similar decennial collections were made by census enumerators at each census up to and including the census of 1900, but because of the time interval between the occurrence of a death and census enumeration, these reports were inaccurate and incomplete.

In 1880 the U.S. Bureau of the Census established a national "registration area" for deaths. This original area consisted of two States—Massachusetts and New Jersey—the District of Columbia, and several large cities having efficient systems for the registration of deaths; by 1900 eight other States had been admitted. For the years 1880, 1890, and 1900, mortality data were received from the States and cities included in this expanding area, but the figures for the entire country were still compiled from the reports of census enumerators.

The annual collection of mortality statistics for the registration area began with the year 1900. In 1902 the Bureau of the Census, which had previously functioned only in census years, was made a permanent agency by an act of Congress. This act authorized the Director of the Bureau of the Census to obtain annually copies of records filed in the vital statistics offices of States and cities having adequate death-registration systems. At that time not all States had enacted laws requiring the registration of deaths, and in many States the existing laws were poorly enforced. The growth of the registration area is indicated in table 6-1.

The death-registration area for 1900 consisted of 10 States, the District of Columbia, and a number of cities located in nonregistration States. In 1900 the

registration area included 40.5 percent of the population of the continental United States. The original registration area was predominantly urban and was characterized by a high proportion of white persons. If the reporting cities located in nonregistration States are excluded, the population coverage of the death-registration States is much lower, only 26.2 percent of the total population of the United States.

Statistics of fetal deaths (the term "stillbirth" was used for many years) were first published for the birth-registration area in 1918. However, they were not included in the reports issued for the succeeding 3 years. Beginning with 1922, statistics of fetal deaths

have been published each year for the birth-registration area.

Table 6-1 presents for each year through 1932 the estimated midyear population of the United States and the estimated midyear population of the States included in the registration system. Both registration areas included the entire United States for the first time in 1933.

Prior to 1940 most of the national mortality tabulations published by the Bureau of the Census were based on data collected from the registration areas. However, beginning with 1940 all published material given in statistical series for the United States prior to

the completion of the death-registration area omits data for registration cities located in nonregistration States and includes only statistics for the registration States. This change decreases the mortality statistics coverage of the United States by the exclusion of cities in nonregistration States, but it has advantages in that more reliable population estimates are available for the registration States than for the registration areas.

Rates for the expanding group of death-registration States are approximations of rates for the entire Nation, and general comparisons over a long period of time can be made. More exact trends for parts of the

United States can be secured through the use of some constant area such as the original registration States or the registration States in 1920.

CLASSIFICATION OF DATA

The principal value of vital statistics data is realized through the presentation of rates which are computed by relating the vital events of a class to the population of a similarly defined class. Vital statistics and population statistics must therefore be classified according to similarly defined systems and tabulated in comparable groups. Even when the variables com-

mon to both, such as geographic area, age, race, and sex, have been similarly classified and tabulated, differences between the enumeration method of obtaining population data and the registration method of obtaining vital statistics data may result in significant discrepancies.

The general rules used in the classification of geographic and personal items for deaths and fetal deaths are set forth in two *Vital Statistics Instruction Manuals*, Part 3, "Classification and Encoder Instructions for Live Birth and Fetal-Death Records, 1970-1971," and Part 4, "Demographic Classification and Encoder Instructions for Death Records, 1969-1971."

The classification of certain important items is discussed on the following pages.

Classification by occurrence and residence

Tabulations for the United States in this report are by place of residence unless stated as by place of occurrence. Before 1970 mortality statistics included all deaths occurring in the United States, with nonresident aliens assigned to place of death. Beginning in 1970 resident mortality data refer to deaths of United States residents only. Tables by place of occurrence include deaths of nonresident aliens, so totals will differ slightly from resident tabulations.

Except for the years 1964 and 1965, deaths of nonresident aliens have been treated as deaths to residents of the exact place of occurrence, which in most instances was an urban area. In 1964 and 1965, deaths of nonresident aliens and residents of Puerto Rico and the Virgin Islands occurring in the 50 States and the District of Columbia were allocated as deaths to residents of the balance of the county in which they occurred.

Residence error.—Results of a 1960 study show that the classification of residence information on the death certificates corresponded closely to the residence classification of the census records for the decedents whose records were matched.¹

A comparison of the results of this study of deaths with those for a previous matched record study of births² shows that considerable improvement in the quality of residence data had taken place

since 1950. The results were the same—an overstatement of events in urban areas by NCHS compared with the U.S. Bureau of the Census classification. The magnitude of the difference was substantially less for deaths in 1960 than it was for births in 1950. Two factors contribute to this difference in magnitude. First, addition in 1956 of an item asking if residence is inside or outside city limits on the standard certificate aided in properly allocating the residence of persons living near cities but outside the corporate limits. The second factor is that there is more likelihood of movement for hospital utilization for births than for deaths.

Geographic classification

The rules followed in the classification of geographic areas for deaths and fetal deaths are contained in the two instruction manuals referred to previously. The geographic code structure for 1970 is given in an instruction manual entitled "Geographic Codes, 1970."

Standard metropolitan statistical areas.—The standard metropolitan statistical areas (SMSA's) and their component counties are those established by the U.S. Office of Management and Budget as of 1970 (except in the New England States) and used by the U.S. Bureau of the Census.

Except in the New England States, an SMSA is a county or a group of contiguous counties containing at least one city of 50,000 inhabitants or more or "twin cities" with a combined population of at least 50,000 in the 1970 census. In addition to the county or counties containing such a city or cities, contiguous counties are included in an SMSA if, according to specified criteria, they are essentially metropolitan in character and are socially and economically integrated with the central city or cities.³

In New England the Office of Management and Budget uses towns and cities rather than counties as geographic components of SMSA's. The National Center for Health Statistics cannot use the SMSA classification for these States because its data are not coded to identify all towns. Instead the metropolitan State economic area (MSEA) established by the Bureau of the Census, which is made up of county units, is used.⁴

⁴For discussion of MSEA's, see U.S. Bureau of the Census, *State Economic Areas*, Washington, U.S. Government Printing Office, 1951, and the first reference cited in footnote 3.

Standard consolidated areas.—For the metropolitan complexes around New York and Chicago, several contiguous SMSA's and additional counties that do not appear to meet the formal integration criteria for SMSA's but do have strong interrelationships of other kinds have been combined into the New York-Northeastern New Jersey and the Chicago-Northwestern Indiana Standard Consolidated Areas.⁵

Metropolitan and nonmetropolitan counties.—Counties included in SMSA's or in New England MSEA's are called metropolitan counties; all other counties are classified as nonmetropolitan.

Population-size groups (formerly "urban" and "rural" areas).—Vital Statistics data for cities and certain other urban places in 1970 are classified according to the population enumerated in the 1970 Census of Population. In this report "Population-size groups" refers to two groups, "Urban places" and "Balance of area." "Urban places" consists of the following places:

1. Each incorporated city and other urban places of 10,000 inhabitants or more.
2. Each town in New England and each township in New Jersey and Pennsylvania that had no incorporated municipality as a subdivision and had either 25,000 inhabitants or more or a population of 10,000 to 25,000 and a density of 1,500 persons or more per square mile.
3. Each county in States other than the New England States, New Jersey, and Pennsylvania that had no incorporated municipality within its boundary and had a density of 1,500 persons or more per square mile. (Arlington County, Virginia, is the only county classified as urban under this rule.)

"Balance of area" consists of all other places.

Before 1964 places were classified as "urban" or "rural." The Technical Appendixes for earlier years discuss the previous classification system.

Age

The age recorded on the death record is the age at last birthday. With respect to the computation of death rates, the age classification used by the U.S. Bureau of the Census is also based on the age of the person in completed years.

Race and color

Deaths in the United States for 1970 are classified for vital statistics as white and as all other. The former includes persons reported as white and those reported as Mexican, Puerto Rican, or Cuban. The latter includes Negro, American Indian, Aleut and

Eskimo, Chinese, Japanese, Hawaiian, and other races. If the racial entry on the death record indicates a mixture of Hawaiian or Part-Hawaiian with other race, the entry is assigned to the classification "Hawaiian and Part-Hawaiian." If race is given as a mixture of Negro with any other race except Hawaiian and Part-Hawaiian, the race is classified as Negro. Entries of other racial mixtures are classified as other races.

Race not stated.—For 1970 the number of death records for which the race was not stated was 3,847 or 0.2 percent of the total deaths. Death records with race entry not stated were assigned to a racial designation as follows: If the preceding record was coded white, the code assignment is made to white; if the code is other than white, the assignment is made to Negro. For years prior to 1964 all records with race not stated were assigned to white except records of residents of New Jersey for 1962-64.

New Jersey, 1962-64.—The State of New Jersey omitted the race item from its certificates of live birth, death, and fetal death in use in the beginning of 1962. The item was restored during the latter part of 1962. However, the certificate revision without the race item was used for most of 1962 as well as 1963. Therefore figures by race or color for 1962 and 1963 exclude New Jersey. For 1964, 6.8 percent of the death records in use for residents of New Jersey did not contain the race item. For that year the not stated events were assigned randomly within each local area to white or Negro on the assumption the distribution of not stated events by race was the same as that of those with race stated.

Fetal deaths

In May 1950 the World Health Organization recommended for adoption for international use the definition of fetal death as "death prior to the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy; the death is indicated by the fact that after such separation, the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles."⁶ The term "fetal death" was defined on an all-inclusive basis to end confusion arising from usage of such terms as still-birth, abortion, and miscarriage.

Shortly thereafter this definition of fetal death was adopted by the National Center for Health Statis-

⁵See footnote 3.

⁶National Office of Vital Statistics: *International Recommendations on Definitions of Live Birth and Fetal Death*. PHS Pub. No. 39. Public Health Service. Washington. U.S. Government Printing Office, Oct. 1950.

tics as the nationally recommended standard for registration purposes. Previously the nationally recommended definition had been "A fetus showing no evidence of life after complete birth (no action of heart, breathing, or movement of voluntary muscle), if the 20th week of gestation has been reached, should be registered as a stillbirth." The new definition has been adopted by about half the States. In most other States, a fetal death is defined as a birth of a minimum gestation period which is not a live birth, and live births are defined in varying detail.⁷

As another step toward increasing the comparability of data on fetal deaths for different countries, the World Health Organization recommended that in classifying fetal deaths for statistical purposes they be grouped as early, intermediate, and late. These groups are defined as follows:

Less than 20 completed weeks of gestation (early fetal deaths)	Group	I
20 completed weeks of gestation but less than 28 (intermediate fetal deaths)	Group	II
28 completed weeks of gestation and over (late fetal deaths)	Group	III
Gestation period not classifiable in groups I, II, and III	Group	IV

Until 1939 the nationally recommended procedure for registration of fetal death required the filing of both a live-birth and a death certificate. In 1939 a separate Standard Certificate of Stillbirth (fetal death) was created to replace the former procedure. This was revised in 1949, 1955, 1956, and 1968 (see figure 6-B). Separate certificates of fetal death are now in use in all States.

Comparability and completeness of data.—State requirements for registration of fetal deaths vary. The majority of States require registration of fetal deaths of gestations of 20 weeks or more. Table 3-1 in Section 3 shows the minimum period of gestation required by each State for death registration. There is substantial evidence that not all fetal deaths for which registration is required are reported.⁸

Underregistration is more of a problem near the lower limit for States having a minimum gestation period requirement. Failure to register fetal deaths

near the lower limit results to a large degree from underestimating the gestation period. This is illustrated by the fact that for areas requiring registration of all fetal deaths, the total number reported for 20-23 weeks is higher than the numbers reported for 24-27 and 28-31 weeks. For most of the other areas, however, the opposite is true.

In order to maximize the comparability of data by year and by State, most of the tables in Section 3 are based on fetal deaths occurring at gestations of 20 or more weeks. These tables also include fetal deaths or not stated or unknown gestation for those States requiring registration at 20 or more weeks only. Before 1969 all fetal deaths of unknown gestation were included. Beginning with 1969 fetal deaths of not stated gestation were excluded for States requiring registration of all products of conception, unless there was evidence, such as high birth weight, that those fetuses were of 20 or more weeks' gestation.

Some liveborn infants who die shortly after birth, particularly those born prematurely who die before the umbilical cord is severed or while the placenta is still attached, may be erroneously reported as fetal deaths. This type of error may be more of a problem in States lacking a precise definition of fetal deaths.

Massachusetts.—Figures for 1967 exclude approximately 100 fetal deaths recorded in Worcester County, Massachusetts, primarily to residents of the city of Worcester. Figures for 1966 and those for 1963 exclude approximately 300 fetal deaths that were recorded in Boston, to residents of Suffolk County, for the most part. Microfilm copies of these records were not received by NCHS, and as a result numbers of fetal deaths for these cities and counties and for the State are understated. The fetal-death ratio for the State is understated by about 8 percent for 1967, and by about 23 percent for 1966.

Period of gestation.—The period of gestation is the number of completed weeks elapsed between the first day of the last menstrual period and the date of delivery, irrespective of whether the product of conception was liveborn or born without evidence of life. The first day of the last normal menstrual period (LMP) is used as the initial date since it can be more accurately determined than the date of conception, which usually occurs 2 weeks after LMP. When the period of gestation is reported in months on the certificate, it is allocated to gestation intervals in weeks as follows:

1-3 months to under 16 weeks
4 months to 16-19 weeks
5 months to 20-23 weeks
6 months to 24-27 weeks
7 months to 28-31 weeks
8 months to 32-35 weeks
9 months to 40 weeks
10 months and over to 43 weeks and over

⁷ For definitions used by the States, see National Center for Health Statistics, *State Definitions of Live Births, Fetal Deaths, and Gestation Periods at Which Fetal Deaths Are Registered*, Public Health Service, Washington, D.C., May 1966.

⁸ Unpublished fetal mortality data contained in a thesis for Harvard School of Public Health, Apr. 1962, by Carl L. Erhardt, Sc.D., Director, Bureau of Records and Statistics, Department of Health, New York, N.Y.

With the adoption of the 1968 revision of the fetal-death certificate and the increased use of the first day of LMP by the reporting areas, the errors in reporting length of gestation have been minimized. The proportion of fetal deaths assigned to gestation of 36 and 40 weeks has diminished, while the proportion of gestations of 37-39 weeks and 41 weeks and gestation length not stated has increased. In 1970 the areas using LMP were as follows:

Alaska	Maine	North Dakota
Arizona	Maryland	Ohio
California	Michigan	Oklahoma
Colorado	Minnesota	Oregon
District of Columbia	Mississippi	Rhode Island
Hawaii	Missouri	South Carolina
Illinois	Montana	South Dakota
Indiana	Nebraska	Tennessee
Iowa	Nevada	Utah
Kansas	New Hampshire	Vermont
Kentucky	New Jersey	Washington
Louisiana	New York	West Virginia
	North Carolina	Wyoming

Birth weight.—In practically all registration areas birth weight is reported in terms of pounds and ounces rather than in grams. However, the metric system has been used in tabulating and presenting the statistics to facilitate comparison with other data published in the United States. The equivalents in pounds and ounces of the gram intervals are as follows:

500 grams or less	= 1 lb. 1 oz. or less
501-1,000 grams	= 1 lb. 2 oz. - 2 lb. 3 oz.
1,001-1,500 grams	= 2 lb. 4 oz. - 3 lb. 4 oz.
1,501-2,000 grams	= 3 lb. 5 oz. - 4 lb. 6 oz.
2,001-2,500 grams	= 4 lb. 7 oz. - 5 lb. 8 oz.
2,501-3,000 grams	= 5 lb. 9 oz. - 6 lb. 9 oz.
3,001-3,500 grams	= 6 lb. 10 oz. - 7 lb. 11 oz.
3,501-4,000 grams	= 7 lb. 12 oz. - 8 lb. 13 oz.
4,001-4,500 grams	= 8 lb. 14 oz. - 9 lb. 14 oz.
4,501-5,000 grams	= 9 lb. 15 oz. - 11 lb. 0 oz.
5,001 grams or more	= 11 lb. 1 oz. or more

Race and color.—The race of the fetus is ordinarily classified to the race of the parents. If the parents are of different races, the following rules apply: (1) When only one parent is white, the fetus is assigned the other parent's race. (2) When neither parent is white, the fetus is assigned the father's race with two exceptions: If the mother is Hawaiian or Part-Hawaiian, the fetus is classified as Hawaiian; if the mother is Negro and the father is not Hawaiian, the fetus is classified as Negro.

When the race of only one parent is missing or ill-defined, the race of the other determines that of the fetus. When race of both parents is missing, the

race of the fetus is allocated as described above in the previous section on race and color.

Total-birth order.—The number of a birth or a fetal death in the total-birth order is the sum of the births and fetal deaths which a mother has had including the birth being recorded. For example, if a mother has previously given birth to two live babies and to one born dead, the next event to occur, whether a live birth or fetal death, is counted as number four in the total-birth order.

In the 1956 and 1968 revisions of the Standard Certificate of Fetal Death, the item on previous fetal loss included all fetal deaths regardless of gestation period. The majority of States have adopted this change on their certificates of birth and of fetal death. In these States the proportion of mothers of first liveborn children reported as having had a previous fetal loss has increased because of this change. For this reason, the data in tables 3-9 and 3-11 are not completely comparable with similar data published for years before 1956.

The following registration areas requested information on all previous fetal deaths (fetuses born dead at any time after conception) on certificates of both live birth and fetal death in use during all or part of 1970:

Alaska	Louisiana	North Carolina
Arizona	Maine	North Dakota
Arkansas	Maryland	Ohio
Colorado	Massachusetts	Oklahoma
Connecticut	Michigan	Oregon
Delaware	Minnesota	Rhode Island
Florida	Mississippi	South Carolina
Georgia	Missouri	South Dakota
Hawaii	Montana	Utah
Illinois	Nebraska	Vermont
Indiana	Nevada	Virginia
Iowa	New Hampshire	Washington
Kansas	New Jersey	West Virginia
Kentucky	New York	Wyoming

In the remaining States, except Pennsylvania, the live-birth and fetal-death certificates requested the number of previous fetal deaths of 20 or more weeks' gestation only. In Pennsylvania, the live-birth certificate requested the number of fetal deaths of 16 or more weeks' gestation, and the fetal-death certificate asked for the number of all previous fetal deaths.

Legitimacy status.—Tabulations with legitimacy as a characteristic include only States which provided for reporting this item on their certificates of live birth and fetal death in 1970. These States are as follows:

Alabama	Maine	Pennsylvania
Alaska	Michigan	Rhode Island
Arizona	Minnesota	South Carolina
Colorado	Mississippi	South Dakota
Delaware	Missouri	Tennessee
Florida	Nebraska	Texas
Hawaii	Nevada	Utah
Illinois	New Hampshire	Virginia
Indiana	New Jersey	Washington
Iowa	North Carolina	West Virginia
Kansas	North Dakota	Wisconsin
Kentucky	Oklahoma	Wyoming
Louisiana	Oregon	

There are no quantitative data on the characteristics of unwed mothers who may misreport legitimacy status of the fetus or who fail to register fetal deaths. Underregistration may be greater in the illegitimate group than in the legitimate.

Age of mother.—The fetal-death certificate asks for the mother's "age (at time of delivery)," and the ages are edited in NCHS for upper and lower limits. When mothers are reported to be below 13 years of age, the fetal-death record is inspected and queried if necessary. Mothers reported to be age 50 and above are considered to have age not stated. Age on all fetal-death records with age of mother not stated is allocated according to the age appearing on the record previously processed for a mother of identical color and parity. Parity in this case refers to the total number of live births and fetal deaths the mother has had previously.

Cause of death

Beginning with data year 1968 the cause-of-death statistics published by the National Center for Health Statistics have been classified in accordance with the *Eighth Revision International Classification of Diseases, Adapted for Use in the United States (ICDA)*,⁹ which is based on the 1965 Revision of the International Classification of Diseases (ICD).¹⁰ The ICDA gives greater detail and specificity in some categories than is provided by the Eighth Revision of the ICD. Complete correspondence between these two classifications was maintained at the three-digit level, but

new four-digit subdivisions were created in various parts of the ICDA. Where necessary, existing four-digit subdivisions are renumbered to accommodate the additional subcategories in logical sequence. In the ICDA, subdivisions which do not correspond exactly with the ICD are identified by asterisks. In this report the four-digit subcategory numbers which differ from those in the ICD are also shown with asterisks.

In addition to specifying that the Classification be used, the World Health Organization recommended special lists for mortality tabulations—the Detailed List, consisting of all three-digit categories; List A, the List of 150 Causes for Tabulation of Morbidity and Mortality; List B, the List of 50 Causes for Tabulation of Mortality; and List P, the List of 100 Causes for Tabulation of Perinatal Morbidity and Mortality. The recommended tabulation lists have been modified for use in the National Center for Health Statistics.

The Each-Cause List is made up of each three-digit category of the Detailed List to which deaths may be assigned and each four-digit subcategory of the ICDA to which deaths may be assigned. For category 412 the fourth digits .1, .2, .3, and .4 are used instead of the fourth digits .0 and .9 which appear in the ICDA. The each-cause table (1-23) does not show the fourth-digit subcategories provided for Motor vehicle accidents (E810-E823). However, these subcategories, which identify persons injured, are shown in the accident tables (Sec. 4). Special fifth-digit subcategories are also used in the accident tables to identify place of accident when deaths from nontransport accidents are shown.

The List of 281 Selected Causes of Death is an extension of List A designed so that with one exception the original groups can be obtained by combining titles. The individual titles in List A for Certain causes of mortality in early infancy are shown as one group title in tables using the List of 281 Selected Causes. The individual categories are shown in tables using the List of 65 Selected Causes of Infant Death, which was created by extending some titles in List P and by combining others. Titles in List P not shown in this list may be found in the each-cause table with the exception of causes of death in List P that are applicable only to fetal deaths.

The List of 69 Selected Causes of Death is an extension of List B; however, certain causes of low frequency in the United States are not shown separately. These causes are Cholera, Typhoid fever, Plague, Diphtheria, Smallpox, Typhus and other rickettsioses, and Malaria.

The List of 34 Selected Causes of Death for Detailed Geographic Areas was created by combining titles in the List of 69 Selected Causes.

These lists were designed to be as comparable as possible to the NCHS lists most recently in use under the Seventh Revision. In several instances this could not be done. No attempt will be made here to enumerate these changes. However, the following changes for the category Major cardiovascular diseases are especially worth noting. This category was entitled Major cardiovascular-renal diseases in the Seventh Revision NCHS lists, but it no longer includes the renal diseases. Also Diseases of veins and lymphatics and other diseases of circulatory system, which was previously included in the subcategory Other diseases of circulatory system, is no longer included.

Effect of decennial list revisions.—The International Lists, in use in this country since 1900, have been revised decennially in order that the disease classification may be consistent with advances in medical science and changes in diagnostic practice. Each decennial revision of the International Lists has produced some break in comparability of cause-of-death statistics. For the first five revisions, the continuity in the mortality trends is not considered a problem of great concern. Van Buren described some of the major shifts in the cause-of-death statistics up to the Fifth Revision (1938) due to changes in the classification of causes of death.¹¹ Dunn and Shackley measured the change in mortality statistics by cause due to the Fifth Revision.¹² This was done by coding mortality records for 1940 by the 1929 and 1938 revisions. The results of the study have been useful in evaluating the effects of the Fifth Revision and changes in the joint-cause selection procedure.

Sixth Revision.—The Sixth Revision of the International Lists of Diseases and Causes of Death was adopted by the World Health Organization in July 1948 and used for mortality data in the United States from 1949 through 1957. This revision represented a more sweeping change than any previous revision. The classification scheme was expanded considerably to provide specific categories for nonfatal diseases and injuries in order to provide a classification which could be used for coding morbidity as well as mortality records.

In addition to the expanded scope of the Sixth Revision of the International Classification, there was a major change in the method of selection of the cause of death for primary tabulation. A large proportion

of death certificates filed annually in the United States report two or more diseases or conditions as causes of death. General statistical practice requires that cases involving more than one cause of death be assigned to a single cause, making it necessary to select the one cause to which the death will be assigned. The method of selection has an important effect upon the resulting statistics.

In 1948 the World Health Assembly adopted, along with the Sixth Revision of the International Lists, a form of medical certification and rules for classification of the underlying cause of death for international use. The form of medical certification in the Standard Certificate of Death is shown in figure 6-A. It is designed to facilitate the selection of the underlying cause of death when two or more causes are recorded. In general if the certification is completed properly, the underlying cause of death entered by the physician is the cause to be tabulated. This procedure, used in the United States beginning with deaths in 1949, differs markedly from that used in previous years. Formerly, definite priority relationships were set up for combinations of causes reported on the death certificate. The single cause to be tabulated was chosen according to these fixed rules.

Comparability between the Sixth and Fifth Revisions.—In order to maintain a time series of mortality rates for comparable causes, the International Conference for the Sixth Revision of the International Lists recommended that deaths for a country as a whole in the year 1949 or 1950 be coded according to both the Sixth and Fifth Revisions. In the United States, 1950 mortality data were used for the dual coding. The differences resulting from the use of the two revisions are expressed by a factor termed the comparability ratio. This is the number of deaths assigned to a particular cause under the Sixth Revision divided by the number of deaths assigned to that cause using the Fifth Revision.^{13,14}

Seventh Revision.—Beginning with 1955 the decennial conferences for revision of the International Lists are held in years ending in 5 rather than later in the decade as had been done previously. This is to make possible the use of the revised classification for mortality data beginning with years ending in 8. The

new cycle provides time to assess the effect of new provisions and variations in interpretation before the next census. Thus stable mortality data will be available for use with the population figures from the decennial census.

Changes in the Seventh Revision were held to a minimum because of the relatively short experience with the Sixth Revision. In compliance with a recommendation of the Expert Committee on Health Statistics, the changes were limited to essential ones and amendments of errors and inconsistencies. Provisions previously contained in an addendum¹⁵ were integrated into the manual.¹⁶ Since these provisions had been used with the Sixth Revision, they did not represent classification changes. The only change made in three-digit categories consisted of rewording a few titles. In a few cases the rewording included redefining morbid conditions classifiable to these categories and transferring certain terms from one category to another. The three-digit categories which were affected are listed in Section 1, Volume I, of *Vital Statistics of the United States, 1958*. There were also a number of changes in four-digit subcategories, consisting mostly of the addition of subdivisions to provide more detailed classification of malignant neoplasms of specified sites. The three-digit categories for which there were additions, deletions, or changes in the four-digit subcategories are also listed in Section 1 of the 1958 report.

The international rules for selecting the cause of death for primary mortality classification were recast for use with the Seventh Revision to simplify them and to organize them from the viewpoint of the coder making the cause-of-death assignment. The intent of the rules remains the same, that is, to code the cause which the medical certifier judged to be the underlying cause starting the train of events leading directly to death. In recasting the rules, some interpretations were modified—mainly those involving selection of the underlying cause for improperly completed certifications. In adapting coding procedures to reporting practices in the United States, some additional changes in interpretations were made.

In the majority of cases, application of the rules for the Sixth Revision and those for the Seventh resulted in the same code assignment. There were some

differences in individual assignments affecting a number of categories. Many of these individual assignments were compensatory and resulted in no detectable discontinuity of trends for various causes of death; the comparability of a number of categories was affected to a limited extent.

Comparability between the Seventh and Sixth Revisions.—In order to estimate the magnitude of the effect of the Seventh Revision upon the comparability of mortality trends for various causes, a 10-percent sample of deaths in 1958 was classified using both the Sixth and Seventh Revisions. The comparability ratios for selected causes and a discussion of the results of this study are published in "Comparability of Mortality Statistics for the Sixth and Seventh Revisions, United States, 1958."¹⁷

Eighth Revision.—The Eighth Revision contains major modifications in several sections of the lists. Also, the international rules for selecting the underlying cause have been simplified. In addition, changes have been introduced in the special rules and decisions which adapt the coding procedures to reporting practices in the United States.

The Detailed List of the Eighth Revision consists of 671 categories of diseases and morbid conditions, 182 categories for classification of the external cause of injury, and 187 categories for characterization of injuries according to the nature of the lesion. These detailed categories are designated by three-digit numbers. There are also four-digit subcategories in the ICDA that provide further specificity or more information regarding etiology or manifestations of the disease. The Classification is arranged in 17 main sections, or chapters. The important changes are summarized for each of these sections in the introduction to the ICDA, pages xxiv-xxviii. Following are some of the many changes made:

Infective and parasitic diseases.—In the Seventh Revision, list titles for diarrheal conditions were scattered over several sections of the Classification. In the Eighth Revision all the Seventh Revision subdivisions for these conditions, including those for infants, are brought together under one category, Diarrheal diseases (009).

Diseases of the nervous system and sense organs.—Vascular lesions affecting central nervous systems (330-334) in the Seventh Revision has been transferred in the Eighth Revision to Section

VII, Diseases of the circulatory system, where they appear as Cerebrovascular diseases (430-438).

Certain causes of perinatal morbidity and mortality.—This section represents an integration of Section XV (Certain diseases of early infancy) and Classification of causes of stillbirth (Y30-Y39) in the Seventh Revision. The age qualifications used in previous revisions to classify the same conditions in or outside this section have been deleted. For example, Pneumonia of newborn (763) of the Seventh Revision is no longer in this section. Instead, it is included in the Eighth Revision with Pneumonia (480-486), to which pneumonias are assigned without regard to age.

Accidents, poisonings, and violence.—A new subsection (E980-E989) has been introduced for the classification of deaths where it was not possible for the certifier to determine whether the injuries were accidentally or purposely inflicted.

Comparability between the Eighth and Seventh Revisions.—In order to measure the degree of discontinuity in cause-of-death statistics resulting from the introduction of the Eighth Revision, provisional estimates of selected comparability ratios based on dual coding of a stratified sample of 1966 death certificates by the Seventh and Eighth Revisions of the International Classification of Diseases were computed. These ratios appear in the *Monthly Vital Statistics Report* of the National Center for Health Statistics, Volume 17, Number 8, Supplement.

Coding in 1970.—The National Center for Health Statistics usually prepares for its cause-of-death coding clerks an instruction manual which contains decisions and interpretations that apply each year. These manuals are revised annually chiefly to bring coding procedures into alignment with new developments in reporting practices and in medical opinions as to the etiology and causal relationship of diseases and to eliminate inconsistencies in coding procedures.¹⁸ No significant coding changes occurred in 1970.

Since 1968 the use of an automated system for obtaining the underlying cause requires special coding procedures in NCHS. (See Quality Control Procedures under Quality of Data.) The automated system was designed to assign the underlying cause according to the international rules just as if a manual process were to be used.

Medical certification.—The use of a standard classification list, although essential for State, regional, and international comparison, does not assure strict comparability of the tabulated figures. A high degree of comparability between areas could be attained only if all records of cause of death were reported with equal accuracy and completeness. The medical certification of death can be made only by a qualified person, usually a physician, a medical examiner, or a coroner. Therefore the reliability and accuracy of cause-of-death statistics are, to a large extent, governed by the ability of the medical attendant to make the proper diagnosis and by the care with which he completes the death certificate.

The quality of the basic data reported on the death certificate is of fundamental importance in the interpretation of cause-of-death statistics. A pilot study was based on a sample of deaths occurring in Pennsylvania during 3 months of 1956. A representative sample of certificates was selected for particular causes of death. Questionnaires were sent to the physicians who had signed the certificates asking for the diagnostic methods and pertinent findings on which the medical certification of death was based. The returns were reviewed along with the original cause-of-death statement and rated for quality (type and amount) of supporting diagnostic information. For 39 percent of the cases the diagnostic data given were sketchy, and for 58 percent the information was considered good or very good. The quality of the diagnostic information varied considerably with the cause of death. It was concluded that in Pennsylvania the diagnostic data for many disease categories provided an adequate base for medical certification of the cause of death.¹⁹

In a later follow-back study conducted by NCHS, a national sample of deaths occurring in July and August 1960 was selected from the 10-percent Current Mortality Sample. A questionnaire was sent to the physician, coroner, or medical examiner signing the death certificate and to hospitals and others suggested by the medical examiner as possible added sources of diagnostic information. Eighty-seven percent of the medical certifiers returned a questionnaire with some kind of response. Of those returned, 14 percent contained no useful information. The forms were reviewed by two cardiologists to determine whether or not the cause of death assigned was supported by the diagnostic information provided by the certifier. The results showed that "for cardiovascular-

renal diseases as a whole, it is estimated that 70 to 75 percent of the deaths so classified may be considered as a reasonable inference or better."²⁰

One index of the quality of reporting causes of death is the proportion of death certificates coded to the Eighth Revision category numbers 780-792, 795, and 796, which are the rubrics for symptoms and ill-defined conditions. While there are cases for which it is not possible to determine the causes of death, this proportion indicates the care and consideration given to the certification by attending physicians. It may also be used as a rough measure of the specificity of the medical diagnosis made by the physicians in various areas and to a small degree the extent to which autopsies are performed and their findings used in determining the underlying cause of death entered on the death certificate. In 1970, 1.3 percent of all reported deaths in the United States were assigned to ill-defined or unknown causes. However, this percentage varied among the States from 0.2 to 7.6 percent.

Ranking causes of death.—The causes included in the List of 69 Selected Causes of Death have been ranked on the basis of the number of deaths assigned to each cause. Two group titles, Major cardiovascular-renal diseases and Symptoms and ill-defined conditions, are not ranked. In addition, category titles that begin with the words "Other" or "All other" are not ranked. The remaining titles are ranked to determine the leading causes of death. When one of the titles that represents a subtotal is ranked, as in the case of Tuberculosis, all forms, its component parts (in this case, Tuberculosis of respiratory system and Tuberculosis, other forms) are not ranked.

Maternal deaths

Maternal deaths are those for which the certifying physician has designated a maternal condition as the underlying cause of death. The maternal conditions are those assigned to Complications of pregnancy, childbirth, and the puerperium (630-678).

QUALITY OF DATA

Completeness of registration

Although every State has adopted a law requiring the registration of births, deaths, and fetal deaths, these laws are not uniformly observed. In most areas practically all births and deaths are registered. For some areas, however, there is enough underregistra-

tion to affect the use of the statistics for certain purposes.

Quantitative information on completeness of death registration is not available. One condition for admission to the national registration areas was a demonstrated registration completeness of at least 90 percent although the method used in testing completeness was subject to considerable error. It is believed that in the past death registration for the United States has been more complete than birth registration, but the difference now may be rather small. There is evidence, however, that in certain isolated areas, incomplete registration is still a problem. For example, a study made in a few selected counties of Tennessee, where the death rates for 1949 to 1951 were unusually low, served to locate a number of unregistered deaths.²¹ A similar situation may exist in other States.

Massachusetts data

The 1964 statistics for deaths exclude approximately 6,000 events registered in Massachusetts, primarily to residents of the State. Microfilm copies of these records were not received by NCHS. Figures for the United States and the New England Division are also somewhat affected.

Quality control procedures

The "Automated Classification of Medical Entities" (ACME), a new computer system for assigning the underlying cause of death which was introduced in 1968, was used for assigning the 1970 underlying causes of death.²² The ACME rules for coding conditions are very specific, fewer in number, and far less complicated than the international rules for selecting the underlying cause of death.²³

The coder produces condition codes which the ACME computer program matches against decision tables to select the underlying cause of death for each record according to the international rules. These decision tables serve two primary purposes. They provide a comprehensive guide for the relationship be-

tween conditions classifiable to different categories in ICDA when applying rules of selection and modification and they also provide decisions used when the underlying cause is assigned by the ACME system. The tables were developed from the decisions and conclusions employed by NCHS in arriving at the underlying causes of death. Relationships between medical conditions involve varying or contradictory opinions. Therefore further refinements of the decision tables will be required. These changes were reflected in the decision table instruction manual²⁴ and will continue to be in future issues.

The coding of all other death data was done simultaneously with record punching from microfilm images of the original certificates. Approximately 64 percent of all records punched were verified on a 10-percent systematic sample. The expected result from this system of verification is that on the average 2.25 percent of the records will contain one or more errors. The rest of the records were verified completely, and the errors remaining are presumably very few.

Except for cause-of-death coding, both systems of verification involve controlling two types of error (coding and punching) at the same time, and the error rates are a combined measure of both types. While it may be assumed that punching errors are randomly distributed across all items on the record, this assumption cannot be made as readily for coding errors. Systematic errors in coding infrequent events may escape detection during sample verification. For cause-of-death coding this is controlled by listing the rare and impossible codes from the computer and reverifying the cause-of-death assignment. This type of error is partially controlled for the other items by reverifying randomly selected lots from each operator's work.

The coding and punching of fetal deaths are verified completely because of their relatively small number.

After completing coding and punching, record counts are balanced against control totals for each shipment of records from a registration area. Impossible codes are selected out during the editing processes on the computer and are either corrected by reference to the source record or adjusted by arbitrary code assignment. All subsequent operations in tabulating and in table preparation are verified either during the computer processing or by statistical clerks.

COMPUTATION OF RATES.

Population bases

The death rates shown in this report were computed on the basis of population statistics published or made available by the U.S. Bureau of the Census. Rates for 1940, 1950, 1960, and 1970 are based on the populations enumerated as of April 1 in the censuses of those years. Rates for all other years are based on the estimated midyear (July 1) population for the respective years. The sources for population data in 1970 are shown in the footnotes of tables 6-1 through 6-3. The populations of the 50 largest SMSA's and their component counties are derived from the Bureau of the Census for 1970.

Rates and ratios based on live births—Infant, neonatal, and maternal mortality rates, and fetal death rates and ratios are computed on the basis of the number of live births instead of the estimated population under 1 year of age.

New Jersey.—As indicated previously, data by race or color are not available for New Jersey for 1962 and 1963. Therefore for 1962 and 1963 the National Center for Health Statistics estimated a population by age, color, and sex excluding New Jersey for rates shown by color. The methodology used to estimate the revised population excluding New Jersey is discussed in the technical appendixes of the 1962 and 1963 reports.

Age-adjusted death rates

Age-adjusted death rates shown in this report are computed by using the distribution in 10-year age intervals of the enumerated population of the United States in 1940 as the standard population. Each figure represents the rate that would have existed if the age-specific rates of the particular year prevailed in a population whose age distribution was like that of the United States in 1940. The rates for the total population and for each color-sex group were adjusted separately, using the same standard population. It is important not to compare age-adjusted death rates directly with crude rates shown in other tables.
