

Monthly Vital Statistics Report

Provisional Data From the CENTERS FOR DISEASE CONTROL AND PREVENTION/National Center for Health Statistics

Births, Marriages, Divorces, and Deaths for April 1994

Mortality Surveillance System pages 4-7
Diabetes mellitus: 45-74 years of age by race and sex
State Maps pages 8 and 9
Diabetes mellitus by sex

Births

According to provisional reports, an estimated 302,000 births occurred in the United States during April 1994. This was an 8-percent decrease from the provisional number of births reported for April 1993 (328,000). The birth rate, 14.1 live births per 1,000 population, was 9 percent lower than the rate of 15.5 for April 1993. The fertility rate, 62.0 live births per 1,000 women aged 15-44 years, was 8 percent lower than the comparable rate for April 1993 (67.5). The seasonally adjusted fertility rate (63.6) was also 8 percent lower than the comparable rate for April 1993 (69.1).

During the first 4 months of 1994, an estimated 1,301,000 births occurred, a 1-percent decrease from the 1,320,000 reported for the first 4 months of 1993. The birth rate for this period decreased by 3 percent from 15.6 in 1993 to 15.2 in 1994. The fertility rate for January-April 1994 was 66.8, 2 percent lower than the rate for the comparable period of 1993 (68.0).

An estimated 4,020,000 live births occurred in the 12-month period ending with April 1994, a decline of 1 percent from the 4,075,000 births reported for the same period a year earlier. The birth rate of 15.5 was 3 percent lower than the rate of 15.9 for the preceding 12 months. The

Provisional Vital Statistics for the United States

[Rates for infant deaths are deaths under 1 year per 1,000 live births; fertility rates are live births per 1,000 women aged 15-44 years; all other rates per 1,000 total population. Data are subject to monthly reporting variation; see Technical notes]

Item	April				January-April				12 months ending with April

NOTES: Figures include revisions received from the States. Twelve-month figures for the current year reflect revisions received for previous months, and figures for earlier years may differ from those previously published.

U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES
Public Health Service
Centers for Disease Control and Prevention
National Center for Health Statistics

fertility rate for the most recent 12-month period was 68.0, 1 percent lower than the rate for the 12 months ending with April 1993 (69.0). These lower rates continue the generally downward trend observed since early 1991.

Natural increase

As a result of natural increase, the excess of births over deaths, an estimated 120,000 people or 5.6 persons per 1,000 population were added to the population during April 1994.

For the 12-month period ending with April 1994, 1,740,000 persons were added to the population. This represented a rate of natural increase of 6.7, 8 percent lower than the rate of 7.3 for the preceding 12-month period. The decline in the rate of natural increase was due to a decrease in the birth rate and a rise in the death rate.

Marriages

There were an estimated 175,000 marriages performed in April 1994 compared with 174,000 in April a year earlier. The marriage rate per 1,000 population for April was 8.3 in 1993 and 1994.

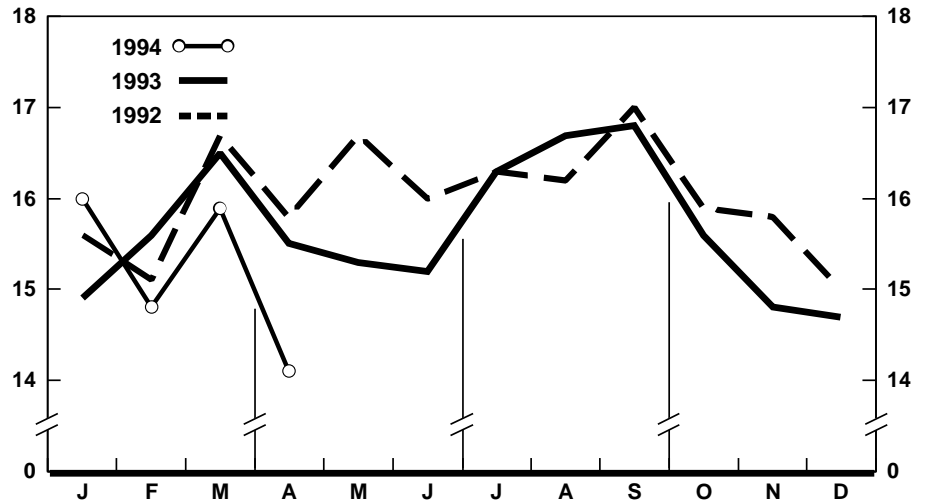

Despite the slight increase for April, the cumulative number of marriages for January–April was 1 percent lower in 1994 (585,000) than in 1993 (589,000). The marriage rate for the 4-month period was 7.0 for both years.

The number of marriages for the 12-month period ending with April 1994 (2,330,000) was 1 percent lower than for the same period a year earlier (2,352,000). The marriage rate for the current 12-month period was 9.0, 2-percent lower than the rate for the preceding 12 months (9.2).

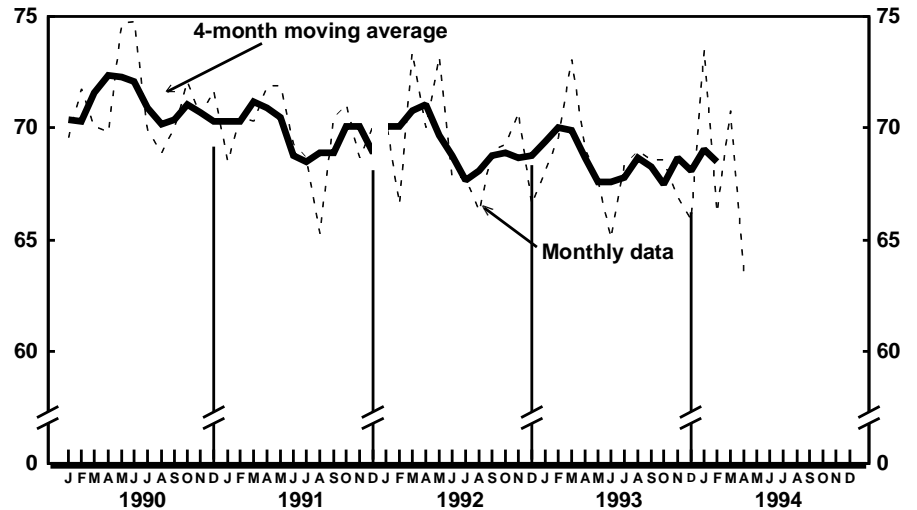

Divorces

Divorces granted in April 1994 numbered 99,000, a slight increase over the number for April 1993 (98,000). The divorce rate for April remained unchanged at 4.6 per 1,000 population.

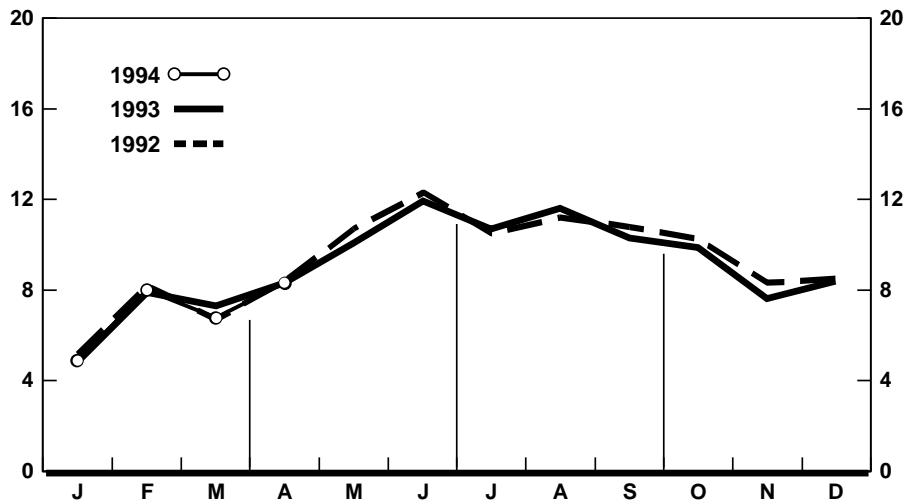

For the first 4 months of 1994, the number of divorces and the divorce rate were virtually unchanged from the comparable period in 1993. The number of divorces dropped less than 1 percent,

Provisional birth rates per 1,000 population by month: United States, 1992-94

Provisional seasonally adjusted fertility rates per 1,000 women aged 15-44 years: United States, 1990-94

Provisional marriage rates per 1,000 population by month: United States, 1992-94

1994 was 515.3 per 100,000 U.S. standard million population, 2 percent higher than the rate of 504.9 for the 12-month period ending with March 1993. Age-adjusted death rates control for changes and variations in the age composition of the population; therefore, they are better indicators than crude rates for showing changes in mortality risk over time and for showing differences between race-sex groups within the population. Among the race-sex groups, the estimated age-adjusted death rates increased for white males, white females, and black males. By age the death rate for the total population increased for the following age groups: 25–34 years, 45–54 years, 65–74 years, 75–84 years, and 85 years and over.

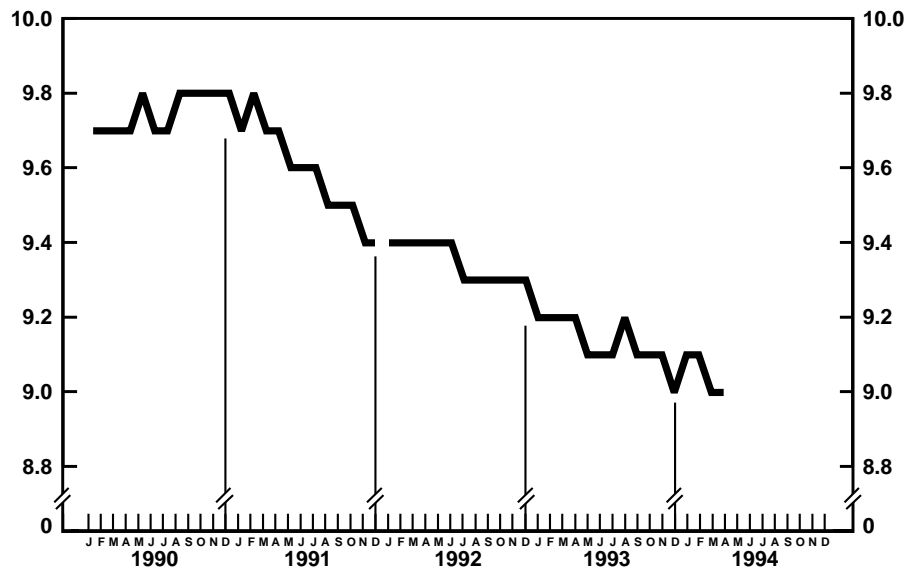

Among the major causes of death, the estimated death rate increased between the two successive 12-month periods for Diseases of heart, Cerebrovascular diseases, Accidents and adverse effects, Chronic obstructive pulmonary diseases and allied conditions, Pneumonia and influenza, Diabetes mellitus, and Human immunodeficiency virus infection.

The death rate for injury by firearms for the 12 months ending with March 1994 was 15.2 per 100,000 population, 5 percent higher than the rate of 14.5 for the comparable 12-month period a year earlier.

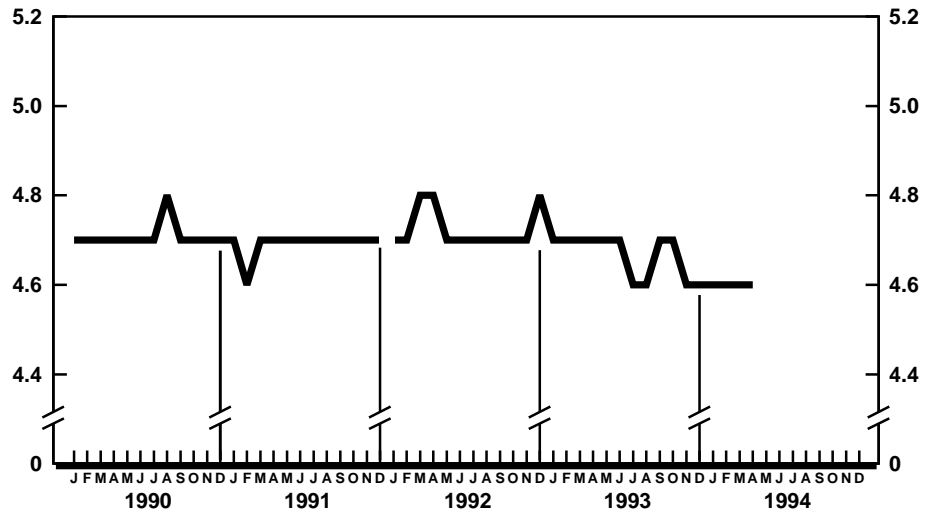

The infant mortality rate for the 12 months ending with March 1994 was 819.4 per 100,000 live births compared with a rate of 830.8 for the same 12-month period a year earlier. The change in the infant mortality rate was not statistically significant. For infants under 28 days, the 12-month rate ending with March 1994 was 534.2 compared with a rate of 523.2 for the 12-month period a year earlier. The infant mortality rate for infants 28 days to 11 months was 288.2 compared with a rate of 307.7 for the 12-month period a year earlier. The changes in the mortality rates for infants under 28 days and for those 28 days to 11 months were not statistically significant.

Mortality Surveillance System

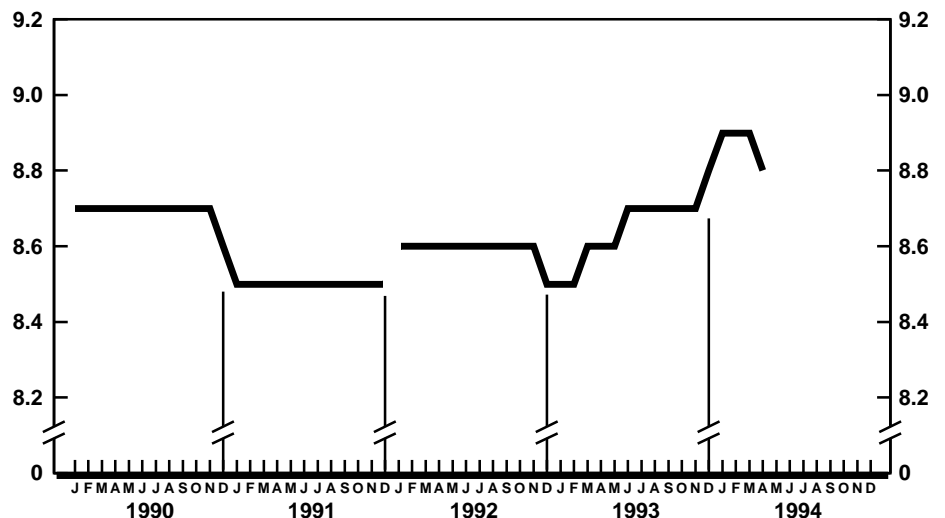

Discussed this month are recent trends in death rates for Diabetes mellitus for the black and white populations by

Provisional marriage rates per 1,000 population for successive 12-month periods ending with month indicated: United States, 1990-94

Provisional divorce rates per 1,000 population for successive 12-month periods ending with month indicated: United States, 1990-94

Provisional death rates per 1,000 population for successive 12-month periods ending with month indicated: United States, 1990-94

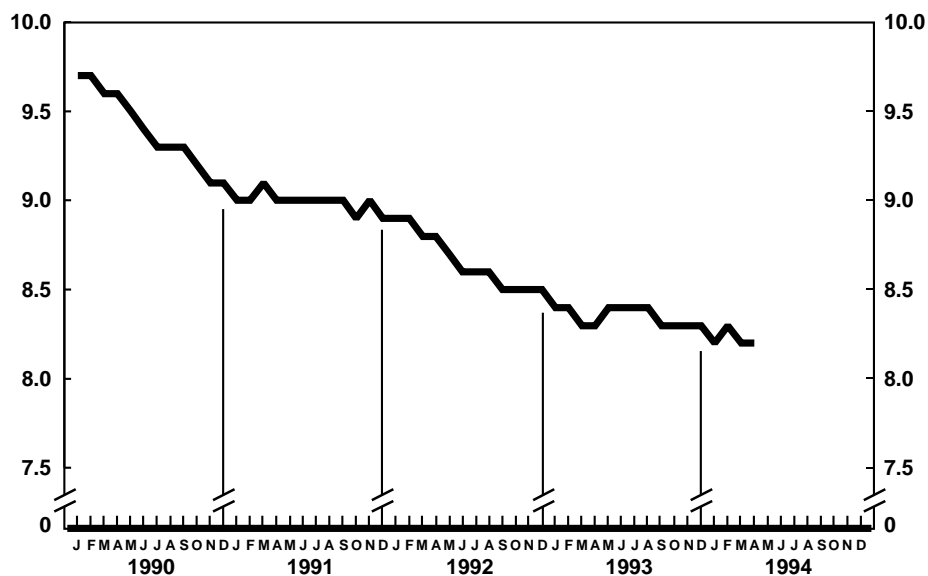

sex for ages 45–74 years. In this issue final mortality data are analyzed for data year 1991 and provisional data from January 1985 to October 1993.

In 1991, the latest year for which final mortality data are available, Diabetes mellitus was the fourth leading cause of death among black women aged 45–74 years. It accounted for 2,899 deaths or 6 percent of all deaths for this age-race-sex group. Among white women aged 45–74 years, Diabetes mellitus was the fifth leading cause of death and accounted for 9,181 deaths or 3 percent of all deaths for this age-race-sex group.

Among black men aged 45–74 years, Diabetes mellitus was the fifth leading cause of death and accounted for 2,036 deaths or 3 percent of all deaths for this age-race-sex group. Diabetes mellitus was the seventh leading cause of death for white men aged 45–74 years and accounted for 9,268 deaths or 2 percent of all deaths for this age-race-sex group.

Based on 1991 final data, the death rate for Diabetes mellitus for black men aged 45–74 years was 2.2 times the rate for white men, while the death rate for black women was 2.7 times the rate for white women of this age group. The rate for white men was 1.1 times the rate for white women, in contrast to blacks, where the rate for black women was 1.1 times the rate for black men.

Trends based on provisional data for Diabetes mellitus for these demographic groups are presented in the Mortality Surveillance System charts and accompanying text that follow.

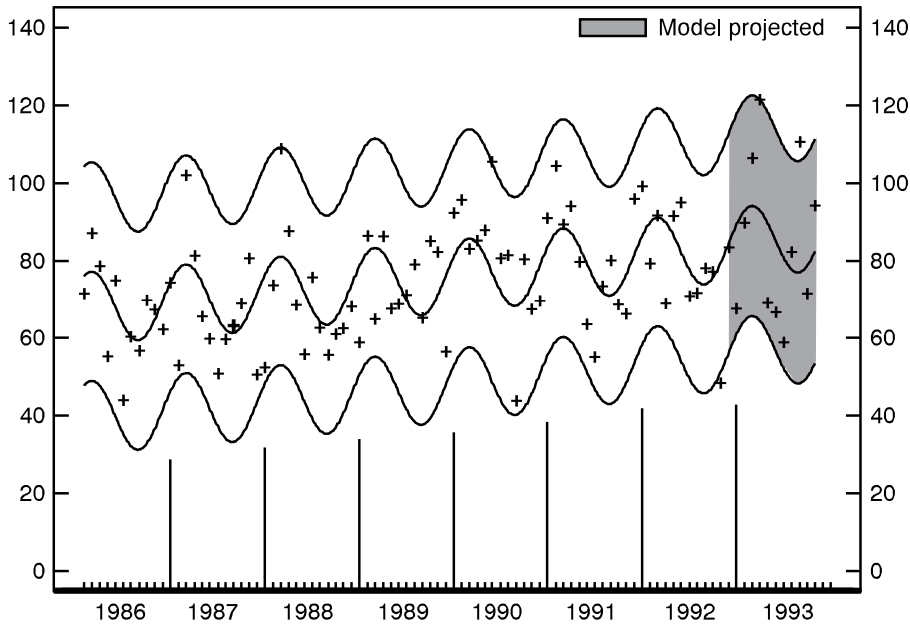

Provisional infant mortality rates per 1,000 live births for successive 12-month periods ending with month indicated: United States, 1990–94

Mortality Surveillance System charts

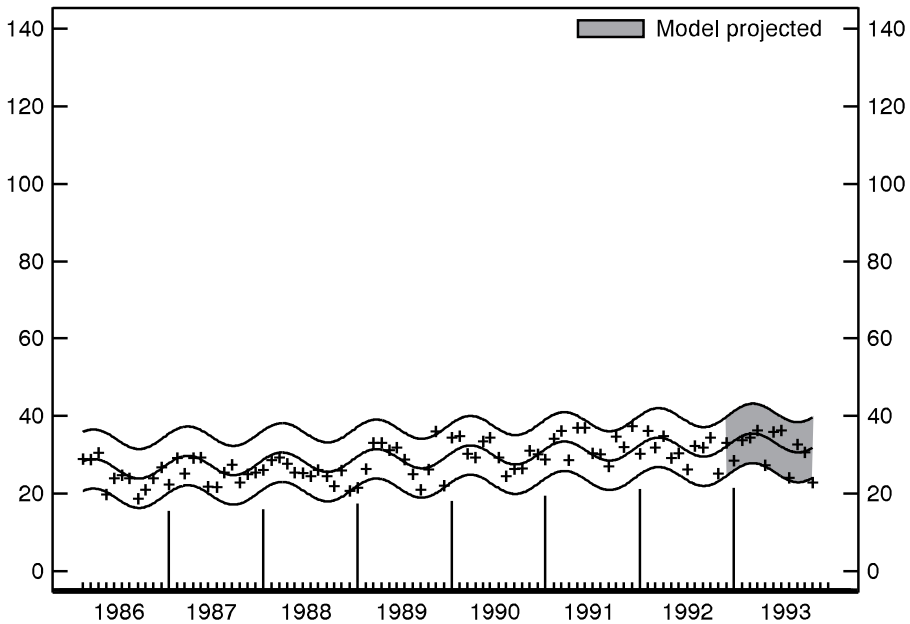

[Observed and fitted provisional monthly death rates and 95-percent prediction intervals. Model fitted using death rates for January 1985–October 1992; projected for November 1992–October 1993. See Technical notes]

Trends in mortality from Diabetes mellitus are presented in the charts below. Reduction of mortality from diabetes-related deaths (deaths from Diabetes mellitus as underlying or contributory cause) is addressed in *Healthy People 2000* (objective 17.9) (2).

Provisional death rates per 100,000 black females 45–74 years of age for Diabetes mellitus, by month: United States, 1986–93

- For the modeled period, provisional death rates increased.
- For the projection period, observed provisional monthly death rates, except for two, fell within 95-percent prediction intervals.
- Mortality shows a seasonal pattern with death rates higher in winter.

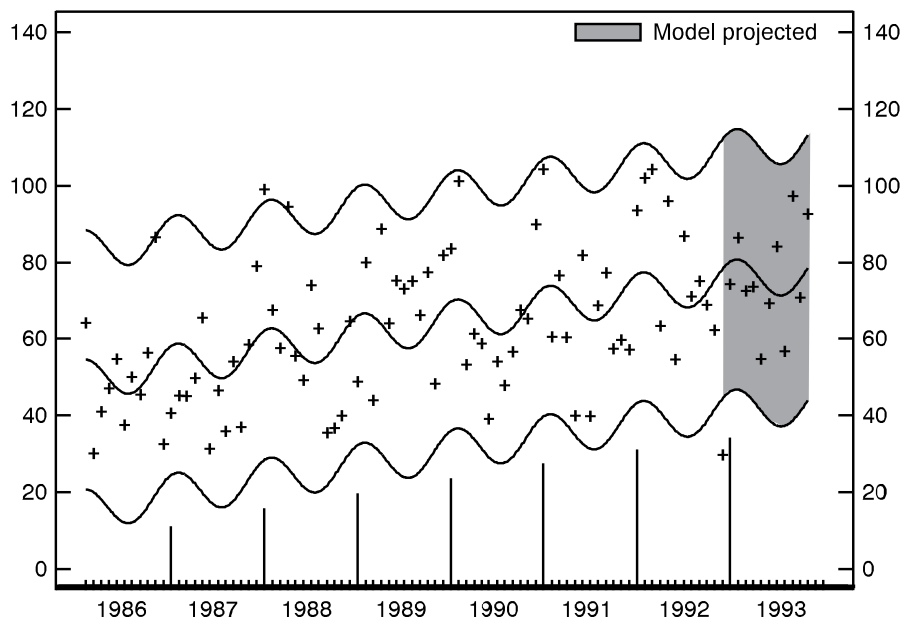

Provisional death rates per 100,000 white females 45–74 years of age for Diabetes mellitus, by month: United States, 1986–93

- For the modeled period, provisional death rates increased.
- For the projection period, observed provisional monthly death rates, except for one, fell within 95-percent prediction intervals.
- Mortality shows a seasonal pattern with death rates higher in winter.

Mortality Surveillance System charts—Con.

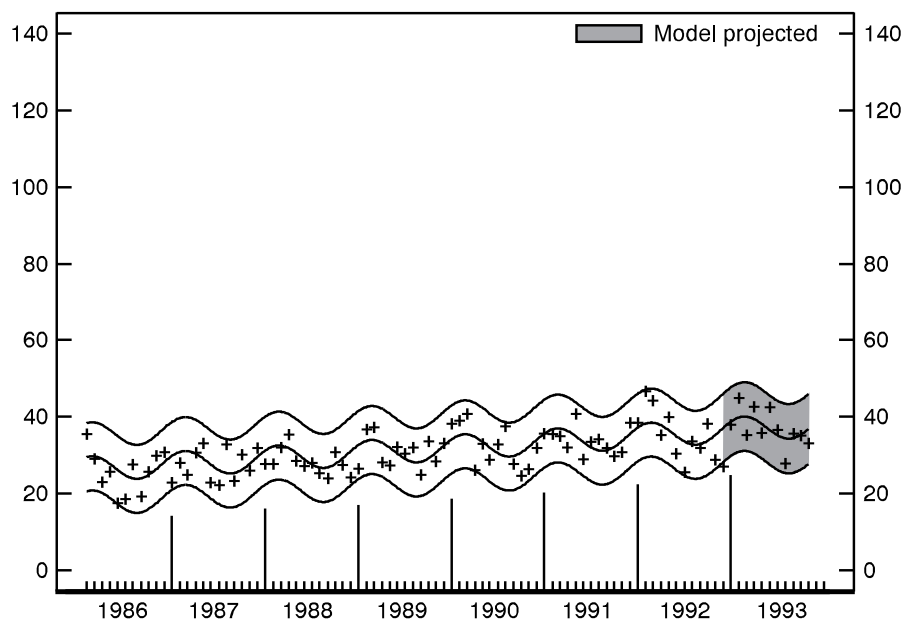

[Observed and fitted provisional monthly death rates and 95-percent prediction intervals. Model fitted using death rates for January 1985–October 1992; projected for November 1992–October 1993. See Technical notes]

Trends in mortality from Diabetes mellitus are presented in the charts below. Reduction of mortality from diabetes-related deaths (deaths from Diabetes mellitus as underlying or contributory cause) is addressed in *Healthy People 2000* (objective 17.9) (2).

Provisional death rates per 100,000 black males 45–74 years of age for Diabetes mellitus, by month: United States, 1986–93

- For the modeled period, provisional death rates increased.
- For the projection period, observed provisional monthly death rates, except for one, fell within 95-percent prediction intervals.
- Mortality shows a seasonal pattern with death rates higher in winter.

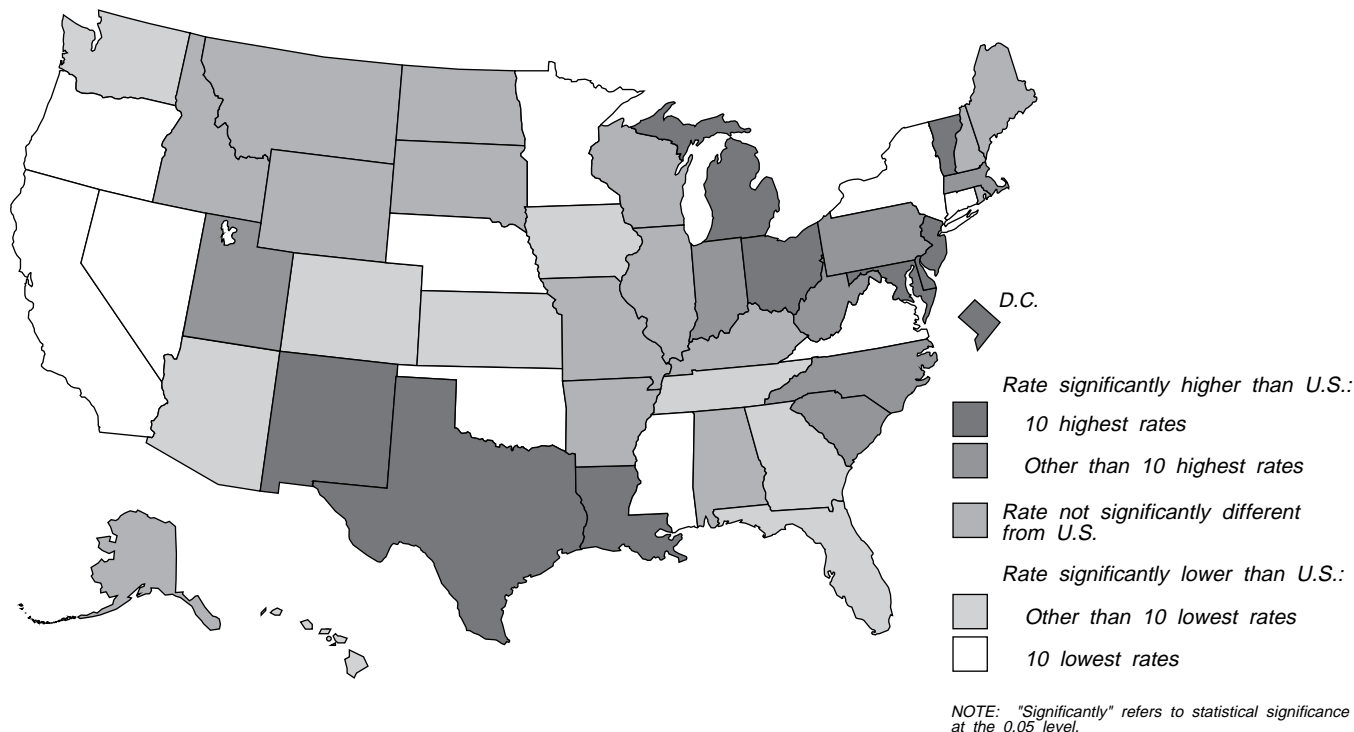

Provisional death rates per 100,000 white males 45–74 years of age for Diabetes mellitus, by month: United States, 1986–93

- For the modeled period, provisional death rates increased.
- For the projection period, observed provisional monthly death rates, except for one, fell within 95-percent prediction intervals.
- Mortality shows a seasonal pattern with death rates higher in winter.

Final 3-year total number of deaths and average annual age-adjusted death rates and 95-percent confidence limits for Diabetes mellitus for males: United States and each State, 1989-91

¹Excludes figures for State(s) shown below as not available.

²Figures for marriages are marriage licenses issued for some counties.

³Figures include adjustments for varying length of reporting periods; see Technical notes.

⁴Figures for marriages are marriage licenses issued.

⁵Figures for divorces include estimates for some counties.

NOTES: Figures include all revisions received from the States. Cumulative figures for the current year reflect revisions received for previous months, and figures for earlier years may differ from those previously published.

Table 4. Provisional number of deaths under 1 year and infant mortality rates: each division and State, 12 months ending with April 1993 and 1994

[Data are estimates by State of residence; see Technical notes. Infant mortality rates are deaths under 1 year per 1,000 live births in specified area]

Table 5. Provisional number of deaths and death rates, by age, race, and sex, and age-adjusted death rates by race and sex: United States, March 1993 and 1994, cumulative figures 1993 and 1994, and 12 months ending with March 1993 and 1994—Con.

[Data are provisional, estimated from a 10-percent sample of deaths. Age-specific rates on an annual basis per 100,000 population in specified group; age-adjusted rates per 100,000 U.S. standard million population; see Technical notes. Due to rounding of estimates, figures may not add to totals. For method of computation and information on standard errors of the estimates, see Technical notes]

¹Includes races other than white and black.

²Death rates under 1 year (based on population estimates) differ from infant mortality rates (based on live births); see table 9 for infant mortality rates.

³For method of computation, see Technical notes.

NOTES: Figures include all revisions received from the States. Cumulative and 12-month figures for the current year reflect revisions received for previous months, and figures for earlier years may differ from those previously published.

Table 6. Provisional number of deaths and death rates for 72 selected causes and Human immunodeficiency virus infection: United States, March 1993 and 1994, cumulative figures 1993 and 1994, and 12 months ending with March 1993 and 1994—Con.

[Data are provisional, estimated from a 10-percent sample of deaths. Rates on an annual basis per 100,000 estimated population. Due to rounding of estimates, figures may not add to totals. For method of computation and information on standard errors of the estimates, see Technical notes. For explanation of the asterisk preceding cause-of-death codes, see Technical notes]

Technical notes

Nature and sources of data

Data in this report are provisional unless otherwise specified and include only events occurring within the United States. Mortality data exclude fetal deaths.

Birth, death, and infant death figures in tables 2 and 4 for each State are estimates by State of residence. These estimates are derived by applying adjustment ratios to the actual counts of certificates for all events occurring in the State and received in registration offices during a 1-month period regardless of date of the event. The adjustment ratios for each data year represent the observed relationship between final State occurrence and residence figures for the three most recent years for which final data were available and are expressed as a single ratio for each State. As in previous years, monthly State marriage and divorce figures represent the actual count of all events occurring in the State (State of occurrence) that were received in the registration offices during the 1-month period. Delay in the receipt of certificates in a registration office may result in a low State figure for a given month followed by a high figure for the month(s) in which the delayed records are received. Data for previous months and cumulative data include revised figures received from the States.

Figures for births, deaths, and infant deaths for California shown in tables 2 and 4 contain adjustments for varying length of State reporting periods. Figures for Texas for all events shown in tables 2-4 also are adjusted for varying length of State reporting periods. The figures for both States are adjusted by the ratio between the number of days in the data month and the number of days in the State reporting period. The adjusted figures are included in the U.S. totals shown elsewhere in this report.

U.S. totals for births, deaths, and infant deaths are based on the State estimates by State of residence and, therefore, in effect, exclude events to nonresidents of the United States. Events to nonresidents of the United

States are included in all marriage and divorce figures. The effect of excluding events to nonresidents from the U.S. totals is small.

Provisional totals for the United States include estimates for State data shown as not available. Provisional totals for births and marriages for the entire United States include adjustments for observed differences between provisional and final monthly figures.

Divorce figures include reported annulments. The monthly national divorce estimate is obtained by multiplying the total for the reporting areas by the ratio observed between the most recent final annual divorce total for the United States and the provisional total for the reporting areas combined.

Random variation—Although the counts in this report are not subject to sampling variability (except the Current Mortality Sample), they may be affected by random variation. When the number of events is small and the probability of such an event is small, considerable caution must be observed in interpreting the data. Such infrequent events may be assumed to follow a Poisson probability distribution. For this distribution a simple approximation may be used to estimate the random variation as follows:

If N is the number of events in the population and R is the corresponding rate, the chances are 19 in 20 that

$$1. N - 2\sqrt{N} \text{ and } N + 2\sqrt{N}$$

covers the "true" number of events.

$$2. R - 2 \frac{R}{\sqrt{N}} \text{ and } R + 2 \frac{R}{\sqrt{N}}$$

covers the "true" rate.

If the rate R_1 corresponding to N_1 events is compared with the rate R_2 corresponding to N_2 events, the difference between the two rates may be regarded as statistically significant at the 0.05 level if it exceeds

$$2 \sqrt{\frac{R_1^2}{N_1} + \frac{R_2^2}{N_2}}$$

Additional information on random variation in numbers of events, rates, and ratios may be found in the technical

appendixes of *Vital Statistics of the United States, 1989*, volumes I and II.

Rates

Rates are on an annual basis and, except for infant mortality rates, are per 1,000 or 100,000 estimated population residing in the United States. The populations used for computing these rates are furnished by the U.S. Bureau of the Census. Rates shown in this report were computed using populations comparable to those used for final data. Monthly rates are based on populations estimated for the specific month. Year-to-date rates are averages of monthly rates that have been weighted by the number of days in the corresponding months. Rates for 12-month periods are the sum of events for the period per population estimated at the midpoint of the period.

Infant mortality rates are deaths under 1 year of age for the specified period (monthly, year-to-date, or 12-month period) per 1,000 or 100,000 live births. Births used for computing monthly and year-to-date infant mortality rates are adjusted for monthly variation in the number of births. Births used to compute 12-month rates do not contain this adjustment. Births used for computing infant mortality rates are not corrected for observed differences between provisional and final monthly figures as described in Nature and sources of data. Because monthly infant mortality rates are based on relatively few events, they are highly variable. Therefore, comparisons of monthly infant mortality rates should be interpreted cautiously; see Random variation.

Age-adjusted death rates are used to compare relative mortality risks across groups and over time. However, they should be viewed as constructs or indexes rather than as direct or actual measures of mortality risk. Statistically, they are weighted averages of the age-specific death rates, where the weights represent the fixed population proportions by age. See chapter 5 of an earlier report (3). The age-adjusted death rates presented in this report were computed by the direct method, that is, by applying age-specific death rates to the U.S. standard million population (4). See also chapter 10 of an earlier report (3). Age groups in table 5 were used to compute the age-adjusted

rates shown in that table. The age-adjusted death rates on which the State maps are based and which are shown with the State maps were computed from average annual age-specific death rates in 10-year age groups for the specified 3-year period. The average annual age-specific death rates were computed by dividing the number of deaths in an age group for the 3-year period by three times the population in that age group estimated at the midpoint of the period (5). It is important not to compare age-adjusted rates with crude rates.

Current Mortality Sample

The Current Mortality Sample (CMS) is a 10-percent systematic sample of death certificates drawn each month after the certificates are counted in the State registration offices. Deaths and death rates for the United States by age, race, sex, and cause are estimated based on the sample. Because of the additional time required to select and process the certificates, data based on the CMS are published 1 month after publication of the U.S. and State counts. Complete information concerning the underlying cause of death sometimes is not available when the sample is drawn. As a result, estimates based on sample counts for certain causes are biased. Correction for bias is not made in this report but is made in the annual summary (issue number 13 in this series) each year.

Estimated numbers of deaths based on the sample were proportionately adjusted to be consistent with estimates based on the count of death certificates received in State registration offices.

HIV infection—Beginning with data for 1987, the National Center for Health Statistics introduced category numbers *042–*044 for classifying and coding Human immunodeficiency virus infection. The asterisk before the category numbers indicates that these codes are not part of the *Ninth Revision of the International Classification of Diseases*. Deaths classified to these categories are included in All other infectious and parasitic diseases in the List of 72 Selected Causes of Death and are also shown separately at the bottom of table 6.

Sampling variability—Because the estimates of deaths and death rates presented in this report (with the exception of total deaths and deaths under 1 year) are based on a sample of death certificates, they are subject to sampling variability. The estimated relative standard error shown in the following table is a measure of the sampling error of the estimated number of deaths (or of the estimated death rate) expressed as a percent of the estimate. The first column refers to monthly estimates; the second, to annual; cumulative year-to-date totals fall between the two.

The chances are about 2 in 3 that the percent difference between an estimate and the result of a complete count is less than the percent shown. The chances are about 19 in 20 that the percent difference is less than twice the percent shown. A figure based on 100 or fewer estimated deaths has a relative standard error of 30 percent or more and is, therefore, considered unreliable. A rate based on 100 or fewer estimated deaths has been replaced by an asterisk.

Unless otherwise specified, comparisons made in the text between death rates based on the CMS were statistically significant at the 0.05 level of significance. Lack of comment in the text about any two rates does not mean

that the difference was tested and found not to be significant at this level.

Mortality Surveillance System—The Mortality Surveillance System (MSS) charts are based entirely on monthly provisional data from the CMS. Where sample size permits, age-race-sex comparisons are made for the causes of death. Where sample size is too small, only age-sex comparisons are made. A time series regression model of the following form was used:

$$Y(t) = A_0 + A_1t + A_2t^2 + C \cos(2\pi t/12) + S \sin(2\pi t/12) + \epsilon_t$$

where

$Y(t)$ = monthly death rate at time t

t = month number

A_0 = coefficient, which, together with C determines the Y -intercept

A_1 = coefficient of t

A_2 = coefficient of t^2

C, S = coefficients of the harmonic terms

ϵ_t = error terms, assumed to be independent and normally distributed with means 0 and constant variances,

and $\cos(2\pi t/12)$ and $\sin(2\pi t/12)$ are 12-month period harmonic functions.

The coefficients of this model were estimated using provisional monthly death rates for January 1985 through the month that is 12 months prior to the latest month shown in the chart. The graph of the estimated equation and 95-percent prediction intervals is shown for January 1986 through the month that is 12 months prior to the latest month shown in the chart; the graph for the subsequent 12 months is projected (6). Symbols in each chart represent actual monthly death rates based on the CMS. In some cases the data are converted by the natural logarithm before fitting the model. For graphical purposes the data are converted back to rates by the inverse of the natural logarithm. This procedure has the advantage of avoiding negative prediction intervals for the model. The models, parameter estimates, and statistical tests for lack of fit are available on request for the charts published in the MSS. Time series

Relative standard errors for estimated numbers of deaths from the Current Mortality Sample expressed as a percent of the estimate

Estimated number of deaths	Relative standard error of estimate (as percent)	
	170,000 estimated deaths each month	2,000,000 estimated deaths each year
10	94.9	94.9
20	67.1	67.1
50	42.4	42.4
100	30.0	30.0
200	21.2	21.2
500	13.4	13.4
1,000	9.5	9.5
2,000	6.7	6.7
5,000	4.2	4.2
10,000	2.9	3.0
20,000	2.0	2.1
50,000	1.1	1.3
100,000	0.6	0.9
200,000	0.6
500,000	0.4
1,000,000	0.2

regression models have been used previously to describe trends in mortality data (7–9). A list of MSS cause-of-death topics and comparable *Healthy People 2000* (2) objectives is presented on the back of this report.

State maps

Unlike other data presented in this report, the State maps are based on final data instead of provisional data. The age-adjusted death rates used to produce the State maps were computed by using a 3-year total number of deaths for 1989–91 and the 1990 census population enumerated as of April 1, 1990 (5). Assigning the States into the given categories on the maps was carried out in two steps: a) determining whether the State age-adjusted death rate differed significantly from the corresponding U.S. rate at the 0.05 level of significance; b) then grouping the State rates found to be significantly different from the U.S. rate into the four categories: 10 highest State rates of those significantly greater than the U.S. rate, remaining State rates significantly greater than the U.S. rate, 10 lowest State rates of those significantly lower than the U.S. rate, and remaining State rates significantly lower than the U.S. rate. Age-adjusted death rates and the corresponding 95-percent confidence intervals are shown in the tables. The symbols † and †† in the tables are used to denote State rates that differ significantly from the U.S. rate at the 0.05 and 0.01 levels of significance, respectively. Different procedures were used to determine tests of statistical significance and confidence intervals, depending on the number of deaths.

For 50 deaths or more, the standard normal Z statistic was used to perform the significance test:

$$Z = (R'_s - R'_{us}) / \sqrt{S^2(R'_s) + S^2(R'_{us})}$$

where

R'_s = age-adjusted rate for

1989–91 for the given State per 100,000 U.S. standard million population

R'_{us} = age-adjusted rate for 1989–91 for the United States per 100,000 U.S. standard million population

$S^2(R'_s)$ = estimated variance of the age-adjusted death rate for 1989–91 for the State

$S^2(R'_{us})$ = estimated variance of the age-adjusted death rate for 1989–91 for the United States

The variance of the age-adjusted death rate was computed in terms of the variances of age-specific death rates (10) under the assumption that the age-specific death rates are binomial proportions (11). The 95-percent confidence limits were estimated as follows:

$$\text{Lower limit} = R'_s - 1.96 \cdot S(R'_s)$$

and

$$\text{Upper limit} = R'_s + 1.96 \cdot S(R'_s)$$

For 1–49 deaths the lower and upper 95-percent confidence limits were estimated as described elsewhere (12). The difference between the State and U.S. age-adjusted rates was determined to be statistically significant at the 0.05 or 0.01 level if the rates' respective 95-percent or 99-percent confidence limits did not overlap.

For zero deaths, the following test statistic (λ) was used to perform the significance test:

$$\lambda = \left[\sum_{x=1}^n M_{x(us)} \cdot P_{x(s)} \right] / 100,000$$

where

$M_{x(us)}$ = age-specific death rate per 100,000 population in the x^{th} age group for the United States

$P_{x(s)}$ = population in the x^{th} age group for the given State

n = number of age groups = 11.

The difference between the State and U.S. age-adjusted rates was determined to be statistically significant at the 0.05 level

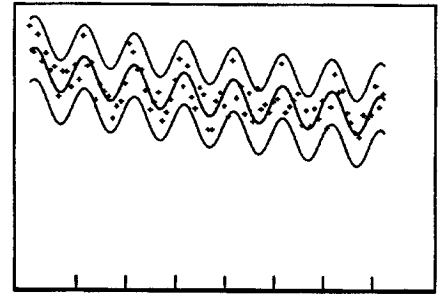

if $3.00 \leq \lambda < 4.61$. The difference between the State and U.S. age-adjusted rates was determined to be statistically significant at 0.01 level if $\lambda \geq 4.61$ (13). For zero deaths, confidence limits for the age-adjusted death rates are not applicable.
