# NATIONAL SURVEY OF AMBULATORY SURGERY 

PUBLIC USE DATA TAPE DOCUMENTATION

#### Abstract

This material provides information for users of the public use data tapes for the National Survey of Ambulatory Surgery (NSAS). NSAS was conducted by the National Center for Health Statistics (NCHS) in 1994, 1995, and 1996. It covered ambulatory surgery procedures performed in hospitals and free-standing ambulatory surgery centers in the United States.

Section I of this document describes the survey and includes information on the history and scope of the NSAS; the survey methodology, data collection and medical coding procedures; population estimates, measurement errors, and sampling errors. Section II provides technical details of the data tapes. Section III provides a detailed description of the contents of each data record.

Appendix A defines certain terms used in this document; Appendix B contains the ICD-9-CM Addenda; Appendix $C$ describes population estimates obtained from the U.S. Bureau of the Census, which allow the user to calculate rates; Appendix D provides unweighted and weighted frequencies for selected variables. Files to accompany Appendix C are provided in LOTUS spreadsheets on a separate diskette accompanying this documentation. Also on the diskette are LOTUS files containing tables of estimated parameters for relative standard error equations, described below in this documentation. These files are named RSEXX.WK4, with the XX replaced by the last two digits of the data year.

## DESCRIPTION OF THE NATIONAL SURVEY OF AMBULATORY SURGERY

INTRODUCTION. This document describes the National Survey of Ambulatory Surgery (NSAS) and provides information for users of the 1994, 1995, and 1996 NSAS public use data files. This survey, conducted by the National Center for Health Statistics (NCHS), covered ambulatory surgery procedures performed in hospitals and in free-standing ambulatory surgery centers in the United States. A brief description of the survey design and data collection procedures is given below. A more detailed description of the survey design, data collection procedures, and the estimation process has been published (1).

HISTORY. The National Survey of Ambulatory Surgery was undertaken to obtain information about the use of ambulatory surgery. Ambulatory, or outpatient, surgery has increased in the United States since the early 1980's. Two major reasons for this increase were advances in medical technology and cost containment initiatives.

On the medical side, many surgeries performed for hospital inpatients have moved to outpatient settings. This is due, in part, to the fact that improvements in anesthesia and better analgesics for relief of pain have made surgery less complex and risky (2). Also, minimally invasive and non-invasive procedures, such as laser surgery, laparoscopy, and endoscopy, have been developed and are being performed with increasing frequency.

On the cost side, concern about rising health care costs led to changes in the Medicare program that encouraged the use of ambulatory surgery (3). In 1982 the Medicare program was expanded to cover care in ambulatory surgery centers. In 1983, a prospective payment system based on diagnosis-related groups (DRG's) was adopted for hospital inpatient care. This system created strong financial incentives for hospitals to perform less complex surgery in an ambulatory setting. In the mid-1980's, the peer review organizations for Medicare established outpatient settings as the norm for certain surgeries and denied Medicare payment for hospital admissions deemed inappropriate or medically unnecessary. Many State Medicaid plans and private insurers followed the lead of the Medicare program and adopted similar policies.

As these changes went into effect, freestanding ambulatory surgery centers increased in number, from 239 centers that performed 380,000 procedures in 1983, to over 1,800 centers performing more than 3.2 million procedures ten years later (4). The number of ambulatory surgery procedures done in hospitals and freestanding settings combined rose from 5.4 million in 1983 to 16.2 million in 1993 (5).

The National Hospital Discharge Survey (NHDS), which has been conducted by the National Center for Health Statistics every year since 1965, includes information on procedures performed on inpatients (6). The NHDS remains a good source of data for surgical procedures, such as open-heart surgery or cesarean sections, that must be done on an inpatient basis. But for surgeries that can be performed on an ambulatory basis, NHDS estimates are incomplete. Thus the National Survey of Ambulatory Surgery was undertaken to provide data on the increasing use of this type of health care.

## SURVEY METHODOLOGY

SOURCE OF THE DATA. The NSAS covered ambulatory surgery procedures performed in hospitals and free-standing ambulatory surgery centers (FSASC).

The hospital universe included noninstitutional hospitals exclusive of Federal, military, and Department of Veterans Affairs hospitals, located in the 50 States and the District of Columbia. Only short-stay hospitals (hospitals with an average length of stay for all patients of less than 30 days) or those whose specialty was general (medical or surgical) or children's general were included in the survey. These hospitals must also have had six beds or more staffed for patient use. This universe definition was the same as that used for the National Hospital Discharge Survey. The sampling frame for the hospital universe consisted of eligible hospitals listed in the 1993 SMG Hospital Market Database (7).

The universe of freestanding facilities included FSASCs that were regulated by the States or certified by HCFA, the Health Care Financing Administration, for Medicare participation. The sampling frame consisted of facilities listed in the 1993 Freestanding Outpatient Surgery Center Database (8) and Medicare-certified facilities included in the HCFA Provider-of-Services (POS) file (9). Facilities specializing in dentistry, podiatry, abortion, family planning, or birthing were excluded. However, these procedures were not excluded from in-scope locations.

SAMPLE DESIGN AND DATA COLLECTION. The NSAS sampled facilities using a multi-stage probability design with some facilities selected with certainty and others sampled with varying selection probabilities. Independent samples of hospitals and free-standing ambulatory surgery centers were drawn. The sample included with certainty facilities which performed a high volume of ambulatory surgeries annually. Non-certainty facilities were selected using a stratified, cluster design, where the clusters were 198 primary sampling units (PSUs) that comprised the sample of PSUs used in the 1985-1996 National Health Interview Survey (NHIS). PSUs were counties or groups of counties, or county equivalents, or towns and townships (the latter in New England and Hawaii).

Noncertainty facilities were stratified by facility type (hospital versus freestanding), ambulatory surgery status of hospitals (i.e. whether or not the hospital performed such surgery), facility specialty, and geographic region. From each stratum containing fewer than six facilities, up to three facilities were selected by means of systematic random sampling, with selection probabilities proportional to size, where size was the number of ambulatory surgeries performed annually. For strata containing six or more facilities, first stage sampling involved selection of 112 PSUs, which were a probability subsample of the 198 PSUs in the 1985-94 NHIS sample. Some of these PSUs were sampled with certainty. Selection of noncertainty PSUs was performed within PSU strata defined within the four geographic regions by the number of people in the 1980 Census of Population and NHIS stratification variables. From each PSU stratum, the PSUs were selected with probability proportional to the projected 1985 population. The hospital sample was clustered within a probability subsample of 112 of those PSUs.

The second stage of the cluster design consisted of selection of noncertainty facilities from the sampled PSUs, using systematic random sampling with probabilities proportional to the annual number of ambulatory surgeries performed. For both hospitals and FSASCs, up to three facilities of each type and specialty were selected from each non-certainty PSU and up to 15 facilities were selected across the combined certainty PSUs in each region. For the stratum of hospitals which, according to the sampling frame data, did not have ambulatory surgery, a national sample of 50 hospitals was selected to permit estimates of surgery in hospitals that either changed their status or differed from frame data. Any sampled facility which performed less than 50 ambulatory surgeries in the year prior to the data collection year was considered out-of-scope for the data collection year.

Within sampled facilities, a sample of ambulatory surgery visits was selected using a systematic random sampling procedure. Selection of visits within each facility was performed separately for each location where ambulatory surgery was performed. These locations included main operating rooms, dedicated ambulatory surgery units, cardiac catherization laboratories, laser procedure rooms, endoscopy and laparoscopy rooms, etc. Locations within facilities that specialized in or were dedicated to inpatients, dentistry, abortion, podiatry, pain block, or small procedures were excluded. However, as mentioned above, these procedures were not excluded from in-scope locations.

Following selection of ambulatory surgery visits, data was abstracted from the medical record for each visit. The Medical Abstract Form used in data collection contained items relating to the personal characteristics of the patient, including birth date or age, sex, race, zipcode, but not name and address; administrative information, including the date of the surgery, dispostion of the patient, and medical record number; principal and other additional expected sources of payment; and medical information, including diagnoses and surgical and nonsurgical procedures performed, as well as types of anesthesia administered and by whom. The medical record number, date of birth, and patient zip code, were confidential information and were not made available to the public.

| RESPONSE RATE. | 1994 | 1995 | 1996 |
| :--- | :---: | :---: | :---: |
|  |  |  |  |
| Number of Sampled FSASCs | 333 | 333 | 332 |
| Number of Sampled Hospitals | 418 | 418 | 418 |
| Total Sampled Facilities | 751 | 751 | 750 |
| Number In-Scope | 617 | 610 | 600 |
| Number Responding | 494 | 489 | 488 |
| Percent of Hospitals Responding | $88 \%$ | $89 \%$ | $91 \%$ |
| Percent of FSASCs Responding | $70 \%$ | $70 \%$ | $70 \%$ |

MEDICAL CODING AND EDIT. The medical information abstracted from the sampled medical records was coded centrally by NCHS contract staff. A maximum of seven diagnostic codes and six procedure codes was assigned for each sampled abstract. The system used for coding the diagnoses and procedures on the medical abstract forms was the International Classification of Diseases, 9th Revision, Clinical Modification, or ICD-9-CM (10).

Following conversion of the data on the medical abstract to computer tape, a final medical edit was accomplished by computer inspection and by a manual review of rejected records. Priority was given to medical information in the editing decision.

Users of the NSAS diagnostic and/or procedure data must take into account annual ICD-9-CM addenda. The addenda lists new codes, new fourth or fifth digits to existing codes, as well as other modifications. Changes go into effect October 1 of the calendar year. However, in order to preserve consistent coding throughout the data year, the NSAS coding for a given data year was consistent with the Addendum which became effective on October 1 of the previous year. Accordingly, Appendix B lists the changes through October 1, 1995.

POPULATION ESTIMATES. Appendix C describes LOTUS spreadsheets accompanying this documentation which provide Census Bureau population estimates of the U.S. civilian resident population as of July I of the calendar year. These population estimates are consistent with those published in Current Population Reports, Series

P-25; however, they are not official population estimates of the Bureau of the Census.
MEASUREMENT ERRORS AND LIMITATIONS OF THE DATA. As in any survey, results were subject to nonsampling or measurement errors, which included errors due to facility nonresponse, missing abstracts, information incompletely or inaccurately recorded on abstract forms, and processing errors.

In a very small number of records, the age or sex of the patient was missing. For these records, a legitimate value was imputed in such a way as to preserve the original, known distribution of the variable. Fewer than two percent of the records had an imputed age or sex value. Forty-two percent of the records were missing a value for race of the patient. No attempt was made to impute for these missing values.

The determination of whether an ambulatory surgery facility was a hospital or a freestanding center was based on the SMG universe from which the facility was selected. In most cases it was apparent whether a facility was a hospital or a freestanding ambulatory surgery center, but some facilities were not easily classified. For example, a "freestanding" facility may have been owned by a hospital but located some distance away. If such a facility was separately listed in the 1993 SMG Freestanding Outpatient Surgery Center Database and was selected into the NSAS sample from this universe, it was considered a freestanding facility.

The distinction between ambulatory and inpatient surgery was not always clear. According to the 1996 NSAS, an estimated 1.9 percent of ambulatory surgery visits were for patients subsequently admitted to the hospital as inpatients. Some of these patients had procedures which were performed exclusively on inpatients, such as coronary artery bypass graft, in addition to diagnostic procedures such as cardiac catheterization. These visits and their suspected "inpatient" procedures were not eliminated from the data file because they were operationally part of the survey design. It is left to the prerogative of the researcher whether or not to include these procedures in an analysis. However, in NCHS publications for the 1994 NSAS, patients discharged to inpatient status were included in estimates of visits and procedures. For the 1995 and 1996 NSAS, these visits were excluded from all published tabulations.

SAMPLING ERRORS. Statistics from the NSAS were derived by a multistage estimation procedure that produced essentially unbiased estimates. The estimation procedure had three basic components: (a) inflation by reciprocals of the probabilities of sample selection, (b) adjustment for nonresponse, and (c) population weighting ratio adjustments.

The standard error of a statistic is primarily a measure of sampling variability that occurs by chance because only a sample rather than the entire universe is surveyed. The relative standard error of the estimate is obtained by dividing the standard error by the estimate itself. When the resulting value is multiplied by 100, the relative standard error (RSE) is expressed as a percent of the estimate. Estimates of sampling variability were calculated with SUDAAN software, which computes standard errors by using a first-order Taylor series approximation of the deviation of estimates from their expected values. A description of the software and the approach it uses has been published (11).

To provide error estimates that would be applicable to a wide variety of statistics, numerous variances were calculated and the best fit formula was derived. The formula was based on an empirically determined relationship between the size of an estimate $X$ and its relative variance. The relative standard error can then be derived by taking the square root of the relative variance. The formulae needed to
perform the calculations of relative standard errors for aggregate statistics and for percents are given below. These formulae use parameter estimates that are applicable to first-listed diagnosis and all-listed procedures, for the total sample and for hospitals and free-standing ambulatory surgery centers separately. Specific parameters have been derived for selected categories of demographic variables, such as males and females, four geographic regions, four standard age groups, and selected expected source of payment groups. Tables containing these parameter estimates are provided in LOTUS files on a separate diskette accompanying this documentation.

## RELATIVE STANDARD ERRORS FOR AGGREGATE ESTIMATES

The relative standard error of an estimate $X[R S E(X)]$ may be calculated from the formula:

$$
\operatorname{RSE}(\mathrm{X})=\operatorname{SQRT}[\mathrm{a}+(\mathrm{b} / \mathrm{X}) \text { ] }
$$

with a and b provided in the accompanying LOTUS tables. When multiplied by 100 , the RSE $(X)$ is expressed as a percent of the estimate.

For example, in 1996 the estimated number of ambulatory surgery visits to hospitals and free-standing ambulatory surgery centers by persons aged 65 and over with a first-listed diagnosis of cataracts (ICD-9-CM code 366) was $1,952,000$ (excluding those visits admitted to hospitals as inpatients). Using the applicable constants for estimates by age given in the accompanying table produces:

$$
\operatorname{RSE}(1,952,000)=.0658
$$

When multiplied by 100, the relative standard error for the estimate of interest becomes 6.58 percent. From this the standard error is obtained by multiplying the relative standard error by the estimate:

$$
\operatorname{SE}(1,952,000)=1,952,000 \text { * } 6.58 \%=128,442
$$

The standard error can be employed to generate confidence intervals for statistical testing. In this example, the $95 \%$ confidence interval for the estimate of the total number visits by persons aged 65 and over with a first-listed diagnosis of cataracts is:

LOWER LIMIT: 1,952,000-2 * 128,442 = 1,695,116
UPPER LIMIT: 1,952,000 + 2 * 128,442 = 2,208,884

## RELATIVE STANDARD ERRORS FOR ESTIMATES OF PERCENTS

Approximate relative standard errors for estimates of percents may be calculated from the accompanying LOTUS tables also. The relative standard error for a percent, $100 \mathrm{p}(0<\mathrm{p}<1)$, may be calculated using the formula:

$$
\operatorname{RSE}(p)=\operatorname{SQRT}\left[b^{*}(1-p) /\left(p^{*} X\right)\right]
$$

where $100 p$ is the percent of interest, $X$ is the base of the percent, and $b$ is the parameter value, $b$, given in the accompanying table. When multiplied by 100, the $\operatorname{RSE}(p)$ is expressed as a percent of the estimate, $p$.

For example, in 1996 the estimated number of ambulatory surgery visits by persons 65 years old and over was 6,998,000 (excluding those admitted to hospitals as inpatients). This is 33.6 percent of the estimated $20,838,000$ visits for that year.

Using the applicable constants from the accompanying tables for estimates by age produces:

$$
\text { RSE }(.336)=0.00655
$$

When multiplied by 100, the relative standard error for the estimate of interest becomes 0.655 percent. From this the standard error is obtained by multiplying the relative standard error by the estimate:

$$
S E(.336)=.336 * 0.655 \%=.0022
$$

The standard error can be employed to generate confidence intervals for statistical testing. In this example, the $95 \%$ confidence interval for the estimate of the percentage of ambulatory surgery visits by persons in the 65 and over age group is:

$$
\begin{aligned}
& \text { LOWER LIMT }=.336-2^{*} .0022=.332=33.2 \% \\
& \text { UPPER LIMIT }=.336+2^{*} .0022=.340=34.0 \%
\end{aligned}
$$

PRESENTATION OF ESTIMATES. Publication of estimates for the NSAS was based on the relative standard error of the estimate and the number of sample records on which the estimate was based. Estimates were not presented in NCHS reports unless a reasonable assumption regarding the probability distribution of the sampling error is possible.

Based on consideration of the complex sample design of the NSAS, the following guidelines were used for presenting the NSAS estimates:

If the sample size was less than 30, the value of the estimate was not reported.
If the sample size was 30-59, the value of the estimate was reported but should not be assumed reliable.

If the sample size was 60 or more and the relative standard error was less than 30 percent, the estimate was reported.

If the relative standard error of any estimate is over 30 percent, the estimate is considered to be unreliable. It is left to the author to decide whether or not to present it. However, if the author chooses to present the unreliable estimate, the consumer of the statistic must be informed that the statistic is not reliable.

HOW TO USE THE DATA TAPE. The NSAS records were weighted to allow inflation to national or regional estimates. The weight applied to each record is found in tape location 21-25. To produce an estimate of the number of visits, the weights for the desired records must be summed.
Appendix D contains unweighted and weighted frequencies for selected variables on the data tape. These may be used as a cross-check when processing the data on the user's system.

Questions. Questions concerning data on the tape should be directed to:

## II. TECHNICAL DESCRIPTION OF TAPE

XX in the data set name may be replaced by the last two digits of the data year, (i.e. 94, for 1994). Data files for each year are contained on separate cartridge tapes.

| Data Year | Number of Records |
| :--- | :--- |
| 1994 | 117,861 |
| 1995 | 121,564 |
| 1996 | 125,433 |

III. RECORD FORMAT: Location and Coding of Data Elements

This section provides detailed information for each sampled record on the tape, with a description of each item included in the record. Data elements are arranged sequentially according to their physical location on the tape record. Data are derived from the abstract form; the SMG Hospital Market Tape is an alternative source of data; some items are computer generated.

* Diagnosis and procedure codes are in compliance with the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM).
For diagnosis codes, there is an implied decimal between the 3rd and 4th digits.
For E-codes, the implied decimal is between the 4th and 5th digits.
For inapplicable 4th or 5th digits of diagnosis codes, a dash (-) is inserted.
For procedure codes, there is an implied decimal between the 2nd and 3rd digits.
For inapplicable 3rd or 4th digits of procedure codes, a dash (-) is inserted.

## APPENDIX A

## DEFINITION OF TERMS

HOSPITALS---Short-stay hospitals or hospitals whose specialty was general (medical or surgical), or children's general. Hospitals must have had 6 beds or more staffed for patient use. Federal hospitals and hospital units of institutions were not included.

FREE-STANDING AMBULATORY SURGERY CENTERS---Facilities listed in the 1993 Freestanding Outpatient Surgery Center Database and Medicare-certified facilities included in the HCFA Provider-of-Services (POS) file. Facilities specializing in dentistry, podiatry, abortion, family planning, or birthing were excluded.

AMBULATORY SURGERY---Scheduled outpatient surgery performed in any of the following locations: general or main operating room, satelitte operating room, cystoscopy room, endoscopy room, cardiac catherterization lab, laser procedures room.

FIRST-LISTED DIAGNOSIS---The coded diagnosis which was listed first on the face sheet of the medical record. The number of first-listed diagnoses was equivalent to the number of ambulatory surgery visits.

PROCEDURES---Surgical or nonsurgical operations, procedures, or special treatments listed by the physician on the medical record. In the NSAS, all terms listed on the face sheet (summary sheet) of the medical record under the caption "operation," "operative procedures," "operations and/or special treatment," and the like were transcribed in the order listed. A maximum of six procedures was coded.

RATE OF PROCEDURES---The ratio of the number of procedures during a year to the number of persons in the civilian population on July 1 of that year.

AGE---The age of the patient on the birthday prior to the date of surgery.
POPULATION---Civilian population was the resident population excluding members of the Armed Forces.

GEOGRAPHIC REGION---Hospitals were classified by location in one of the four geographic regions of the United States corresponding to those used by the U.S. Bureau of the Census:

| NORTHEAST | MIDWEST | SOUTH | WEST |
| :--- | :---: | :---: | :---: |
| Maine | Michigan | Delaware | Montana |
| New Hampshire | Ohio | Maryland | Idaho |
| Vermont | Illinois | District of Columbia | Wyoming |
| Massachusetts | Indiana | Virginia | Colorado |
| Rhode Island | Wisconsin | West Virginia | New Mexico |
| Connecticut | Minnesota | North Carolina | Arizona |
| New York | lowa | South Carolina | Utah |
| New Jersey | Missouri | Georgia | Nevada |
| Pennsylvania | North Dakota | Florida | Washington |
|  | South Dakota | Kentucky | Oregon |
|  | Nebraska | Tennessee | California |
|  | Kansas | Alabama | Hawaii |
|  |  | Mississippi | Alaska |
|  |  | Arkansas |  |
|  |  | Louisiana |  |
|  |  | Oklahoma |  |

#### Abstract

APPENDIX B The International Classification of Diseases, 9th Revision, Clinical Modification was the system used for coding medical data in the NSAS. Each year the ICD-9-CM classification system undergoes updating. The changes include assignment of new diagnostic and procedure codes, fourth and fifth digit expansion of codes, as well as code deletions. These changes are published in an Addendum and become effective October 1 of the calendar year. Addenda are developed by the ICD-9-CM Coordination and Maintenance Committee and approved by the Director of NCHS and the Administrator of the Health Care Financing Administration.

All data collected for the NSAS were coded using the third edition of the ICD-9-CM. Because the Addendum changes go into effect in October of the calendar year, estimates for codes that have been changed would not be accurate, as the original and the revised code would be applicable for only part of the year. However, to circumvent this problem, in the NSAS it was decided not to implement the October coding changes during the calendar year they were introduced. Instead, because NSAS data represent the calendar year, coding for 1994, 1995, and 1996 is consistent with the Addendum that went into effect in October of the previous year and those codes were used throughout the entire data year. This was done to avoid the problem of partial year estimates being mistaken for full year estimates.

In order to assist users in data retrieval, a conversion table is provided that shows for each new code, its date of introduction and the previously assigned code equivalent, which had been used for reporting the selected diagnosis or procedure prior to issuance of the new code. This table shows coding changes up to October 1995.

## DIAGNOSIS CODES

|  | Effective |  |
| :---: | :---: | :---: |
| Current code(s) assignment | October 1 | Previous code(s) assignment |
| 005.81 | 1995 | 005.8 |
| 005.89 | 1995 | 005.8 |
| 008.00-008.09 | 1992 | 008.0 |
| 008.43-008.47 | 1992 | 008.49 |
| 008.61-008.69 | 1992 | 008.6 |
| 041.00-041.09 | 1992 | 041.0 |

## APPENDIX C

This appendix describes the population files included on the diskette accompanying this documentation. These files contain Census Bureau estimates of the U. S. civilian resident population, as of July 1, for the years 1994 through 1996. There are two types of files, named either 1YRxx.WK1 or REGxx.WK1. To select a given year, the "xx" can be replaced by the last two-digits of the year desired between 1994 and 1996 (e.g. 94). These estimates are consistent with the population estimates published in Current Population Reports, Series P-25.

There are separate tables for estimates disaggregated by sex, race, and single-year age groupings and those disaggregated by sex, region, and single-year age groupings. All figures are unrounded. These population estimates have been adjusted based on the 1990 decennial census.

LOTUS tables to accompany Appendix C :

| 1YR94.WK1 | Civilian Population of the United States, Estimates by Age, Sex, and <br> Race, July 1, 1994 |
| :--- | :--- |
| 1YR95.WK4 | Civilian Population of the United States, Estimates by Age, Sex, and <br> Race, July 1, 1995 |
| 1YR96.WK4 | Civilian Population of the United States, Estimates by Age, Sex, and <br> Race, July 1, 1996 |
| REG94.WK1 | Civilian Population of the United States, Estimates by Age, Sex, and <br> Region, July 1, 1994 |
| REG95.WK4 | Civilian Population of the United States, Estimates by Age, Sex, and <br> Region, July 1,1995 |
| REG96.WK4 | Civilian Population of the United States, Estimates by Age, Sex, and |
|  | Region, July 1,1996 |

## APPENDIX D

The material provided in this appendix is for users who wish to verify their data tabulations. Unweighted and weighted frequencies for selected variables are given for each data year, i.e. 1994, 1995, and 1996. If any discrepancies are found between the frequencies given below and the user's calculations, please notify Jen Popovic at 301.458.4321 or jpopovic@cdc.gov.
