Final Data From the National Center for Health Statistics

## Advance Report of Final Natality Statistics, 1981

## Births and birth rates

There were $3,629,238$ registered live births in the United States during 1981, less than 1 percent more than the $3,612,258$ births recorded in 1980. This was the smallest annual increase
in the number of births since 1978. Provisional data for 1982 indicate an increase of about 2 percent over the final figure for 1981 (figure 1).

Declines of 1 percent between 1980 and 1981 were observed for other measures of fertility (table 1). The birth rate

Figure 1. Live births and fertility rates: United States, 1920-81
was 15.8 live births per 1,000 total population in 1981 , about 1 percent below the rate for 1980 (15.9). Provisional statistics for 1982 indicate a small increase of about 1 percent in the birth rate.

The fertility rate for 1981 was 67.4 live births per 1,000 women aged 15-44 years, I percent below the 1980 rate of 68.4. A very slight increase in the fertility rate, less than 1 percent, is indicated for 1982 , according to provisional data. The birth and fertility rates declined between 1980 and 1981 because the increase in the number of births was more than offset by the increases in the estimated populations used as denominators for the rates.

Birth rates for women of all ages except 10-14, 35-39, and 45-49 years declined between 1980 and 1981, with the declines ranging from 1 percent for women aged 15-19, 25-29, and $30-34$ years to 3 percent for women aged $20-24$ and 40-44 years. (See figure 2 for birth rates by age of mother and tables 2,3 , and 4 for births and birth rates by age of mother.) Women aged $35-39$ years were the only age group to show an increase ( 1 percent) in fertility between 1980 and 1981. Rates for women 10-14 and 45-49 years were unchanged. The year 1981 marks the first time that the rate for women aged 30-34 years has declined since 1975. Between 1975 and 1980 the rate for these women had increased 18 percent.

The general decline in fertility according to age of mother is reflected in similar declines in birth rates by live-birth order (figure 3 and table 5). Declines were observed for first through fourth and sixth and seventh order births. Rates fell by 1 percent for second and third births, by 2 percent for first births, by 3 percent for fourth births, and by 10 percent for sixth and seventh order births. Rates for fifth and eighth and higher order births were unchanged. The rates for first through third order births had increased annually between 1978 and 1980.

The overall decline of 2 percent in the first birth rate tends to obscure widely divergent trends in these rates by age of mother. The first birth rate declined by almost 3 percent for women aged 20-24 years and increased for women 25-44 years of age with larger increases as age of mother advanced: 2 percent for women aged 25-29 years, 4 percent for women aged 30-34 years, 8 percent for women aged 35-39 years, and 33 percent for women aged 40-44 years. The increases in first birth rates for women in their thirties reflect a continuation of a pattern observed since $1972 ;{ }^{1}$ however, the 4 -percent rise in the rate for women aged $30-34$ years is the smallest increase measured since 1975.

It is evident that the pattern of delayed childbearing observed in the United States since the early 1970's has continued, although at a somewhat slower rate of increase between 1980 and 1981. Between 1972 and 1981 the first birth rate for women in their early thirties almost doubled, increasing from 7.0 first births per 1,000 women aged $30-34$ years to 13.3 , while the rate for women aged $25-29$ years rose by 33 percent, from 29.2 to 38.8 .

Increases in birth rates for second order births between 1980 and 1981 were confined to women aged 30-34 (1 percent)
and 35-39 years ( 7 percent). Second order birth rates for women in their thirties also increased substantially between 1972 and 1981, by 55 percent for women $30-34$ years, and by 45 percent for women aged $35-39$ years.

Fertility rates for white and black women declined between 1980 and 1981. The rate for white women was 63.9 births per 1,000 women aged $15-44$ years, 1 percent below the 1980 rate of 64.7 . The fertility rate for black women was $85.4,3$ percent under the rate for $1980,88.1$. Birth rates declined by 3 percent or less for white women in age groups 15-34 years. A 1-percent increase was observed in the rate for white women aged 35-39 years, while the rates for women 40-44 and 45-49 years were unchanged. Birth rates for black women declined at every age except 45-49, which was unchanged, with the declines ranging from 1 percent for ages $25-29$ and 35-39 years to 5 percent for young teenagers $10-14$ years old.

First birth rates for white women declined by 3 percent for women 15-24 years. Rates for women $25-39$ years increased by 2 to 8 percent, while rates for women $40-49$ years were unchanged. Among black women, the only first order rates to increase were for women 25-29 (3 percent) and 40-44 years (33 percent).

Increases in both first and second order birth rates for women aged $30-39$ years were relatively small between 1980 and 1981 in comparison with the trends during the 1970's. This suggests that the tendency for women to begin motherhood at later ages is perhaps not as strong now as it was during the late 1970's, although women who have been delaying childbearing may be postponing their first births until their mid or late thirties rather than until their late twenties and early thirties as was true just a few years ago. Further delay of motherhood by these women may reduce the number of children they ultimately have and may result in a greater level of unintended childlessness as these women learn that they have impairments in their ability to bear children that are difficult or impossible to correct. ${ }^{2}$

The total fertility rate indicates the number of births that 1,000 women would have if they experienced throughout their childbearing years the set of age-specific birth rates observed in a given calendar year. It shows the implications of current levels of fertility for completed family size. If the age-specific birth rates of 1981 were to prevail over the entire childbearing period for a given group of 1,000 women, they would bear $1,815.0$ children. This is 14 percent below the level considered necessary for a given generation to exactly replace itself in the population $(2,110)$. The total fertility rate for white women, $1,726.0$, is well below replacement level, while the rate for black women, $2,206.0$, is slightly above the replacement level.

In recent years there has been a sizable increase in births to women of certain specified racial groups, reflecting the substantial increase in population due to immigration among these groups. For example, the number of Chinese births increased by 9 percent between 1980 and 1981, from 12,792 to 13,900 . Between 1978 and 1981, the number of Chinese births rose by 24 percent. Similarly, the number of "Other Asian or Pacific Islander" births, comprising principally births to Asian Indian,

Note: Beginning 1959 trend lines are based on registered live births; trend lines for 1955-1959 are based on live births adjusted for underregistration

Figure 2. Birth rates by age of mother: United States, 1955-81

Figure 3. Birth rates by live-birth order: United States, 1955-81

Cambodian, Korean, Laotian, Thai, and Vietnamese persons (but excluding Japanese, Filipino, and Hawaiian births), has increased considerably in recent years. These births numbered 47,457 in 1981, 21 percent more than in $1980(39,224)$ and 93 percent more than in $1978(24,597)$.

The total number of births increased in six geographic divisions and declined in three (table 6). The increases were 1 percent in the Middle Atlantic and South Atlantic Divisions; 2 percent in the New England, West South Central, and Mountain Divisions; and 4 percent in the Pacific Division. The number of births declined by $1-3$ percent in the East North Central, West North Central, and East South Central Divisions. Increases and decreases were evenly divided among the 50 States and the District of Columbia. The number of births rose in 26 States and fell in 24 States and the District of Columbia.

Birth rates increased in only three divisions: New England and Middle Atlantic (1 percent each) and Pacific ( 2 percent). Rates declined by 1-4 percent in the remaining six divisions. The largest increases in the number of births and the birth rate were in the Pacific Division, while the greatest declines were observed in the East South Central Division. Declines in birth rates by State exceeded increases. Rates declined by 1-5 percent for 29 States and the District of Columbia, increased by 1-3 percent for 17 States, and were unchanged for Arizona, Maine. New Mexico, and Vermont.

## Sex ratio

The sex ratio at birth in 1981 was 1,052 male births per 1,000 female births, virtually unchanged from the 1980 ratio of 1,053 (table 7). The ratio has been 1,052 or 1,053 since 1976.

The sex ratios for white and black births have similarly remained within a narrow range. Since 1976 the ratio for white births has been 1,057-1,058, and for black births, 1,027-1,029. Ratios for other specified race groups have traditionally been more variable from year to year.

## Month of birth

The monthly occurrence of births has shown a consistent pattern for many years, with the peak months generally August or September (table 8). Removal of the seasonal component from the monthly birth and fertility rates facilitates the observation of the underlying trends. Seasonally adjusted fertility rates in 1981 showed no consistent pattern; rates were highest in April, June, and July. Provisional data for 1982 again exhibit no particular pattern, except that the rates in the last quarter of the year were generally higher than those in the first quarter.

## Place of delivery and attendant at birth

The overwhelming majority, 99.0 percent, of babies born in 1981 were delivered in hospitals, as has been true for many years. Black infants were slightly more likely than white infants to be delivered in hospitals ( 99.2 percent compared with
98.9 percent) (table 9). Physicians attended 97.2 percent of all hospital deliveries in 1981 compared with 97.9 percent in 1980. The proportion of midwife-attended births in hospitals increased from 1.4 percent in 1980 to 1.5 percent in 1981. Comparisons between 1980 and 1981 are affected by the relatively large increase in the number of births for which the attendant at birth was not specified (table 10).

The trend toward more births delivered by midwives both in and out of hospitals continued in 1981. Although the numbers of such births are still relatively small, they have increased substantially in recent years. In 1981, 55.537 babies delivered in hospitals were attended by midwives compared with 51,576 in 1980 and 44,496 in 1979. Midwife-attended deliveries occurring out of hospitals numbered 12,754 in 1981 compared with 11,093 in 1980 and 10,363 in 1979 (table 10).

There were increases for both white and black babies attended by midwives in 1981, but the increase was much greater for white ( 11 percent) than for black births ( 6 percent). Among white births, the increase was substantial in midwife-attended, out-of-hospital deliveries-up 17 percent-compared with a 10 -percent increase in midwife-delivered births in hospitals. Among black infants, there was an increase only in midwife deliveries occurring in hospitals ( 6 percent).

## Age of father

The birth rate for men in 1981 was 56.3 live births per 1.000 men aged $15-54$ years, 1 percent below the 1980 rate of 57.0 (see table 11 for basic data and table 12 for birth rates by age of father). The rates for both white and black men also declined. For white men the rate fell by 1 percent, from 52.9 in 1980 to 52.3 in 1981, while for black men the rate declined by 3 percent, from 83.8 to 81.2.

Rates declined by $1-4$ percent for men in all age groups under 35 years and for ages $40-44$ years. The rate for men 35-39 years increased 1 percent, while the rates for men 45-49 and 50-54 years increased 3-5 percent. The birth rate for men aged 55 years and older was unchanged. The changes by age of father were similar for white and black men through age 34, except that the declines for black men exceeded those for white men. At ages 35-49 years there was no consistent pattern in the rates by race.

## Weight at birth

In 1981, as in 1980.6.8 percent of all births were classified as being of low birth weight. Low birth weight is defined as less than 2,500 grams ( 5 pounds 8 ounces), in accordance with the definition established in the International Classification of Diseases, Ninth Revision.

The proportions of low birth weight for both white and black infants were also unchanged in 1981; the racial differential therefore remains substantial. In 1980 and 1981, 5.7 percent of white infants and 12.5 percent of black infants were of low birth weight.

Babies born to mothers aged 25-29 and 30-34 years are least likely to be of low birth weight, while infants born to teenagers and mothers aged 40 years and over are most at risk of low birth weight, continuing a pattern that has been observed for many years. In 1981, 5.8 percent of births to women 25-29 and $30-34$ years were of low birth weight compared with 14.0 percent of births to girls under 15 years of age (table 13).

The median birth weight of infants born in 1981 was 3,360 grams (equivalent to approximately 7 pounds 7 ounces), unchanged from the medians for 1979 and 1980. The medians for white and black infants were the same as in 1980-3,410 grams for white births (about 7 pounds 8 ounces) and 3,170 grams for black births ( 7 pounds). The racial difference in birth weight of 240 grams is equivalent to about $8 \frac{1}{2}$ ounces.

The number and percent of low-birth-weight infants by race for each State are shown in table 14. There is considerable variation in the percent low birth weight from State to State within each racial group. Much of this variation is reduced when the States with relatively few black births are excluded from the comparison.

## Multiple births

There were 71,434 live births in multiple deliveries (such as twins, triplets, and quadruplets) during 1981, an increase of 3 percent over the 69,676 plural births reported in 1980. Almost all ( 98 percent) of the multiple births in 1981 were live births in twin deliveries ( 70,049 births). The multiple birth ratio was 19.7 live births in multiple deliveries per 1,000 total live births, an increase from the 1980 ratio of 19.3. Between 1978 and 1980 the ratio had declined from 19.6 to 19.3.

Multiple birth ratios increased for both white and black births from 1980 to 1981. The ratio for black births continued to be higher than for white births, 24.7 compared with 18.8 .

As in previous years, multiple birth ratios in 1981 increased as age of mother advanced, generally up through ages 35-39 years. The ratio for births to mothers aged $35-39$ years was $25.5,85$ percent above the 13.8 ratio for births to teens $15-19$ years old. This pattern was observed for both white and black births, but the ratio for black births was higher than for white births at every age.

## Births to unmarried women

National statistics on births to unmarried women are derived from two sources. For 41 States and the District of Columbia, marital status of mother is reported directly on the birth certificate; for the remaining 9 States, which lack such an item, marital status is inferred from a comparison of the child's and parents' surnames. This procedure (described in the Technical notes) was initiated with the 1980 data year, and represents a significant departure from the method used prior to 1980 to prepare national estimates of births to unmarried women. Because data derived from the new procedure are now available for 2 years,
changes in the incidence of nonmarital childbearing between 1980 and 1981 can be described without concern for the effect of the methodological change on the statistics.

There were 686,605 births to unmarried women in 1981, a 3-percent increase over the 665,747 reported in 1980 (table 15). This was the smallest annual increase in the number of nonmarital births since 1974.

Increases occurred for births to both white and black unmarried women, but the increase was much larger for white births. There were 337,050 white births, 5 percent more than reported for $1980(320,063)$, and 328,879 black births, 1 percent more than the 1980 total $(325,737)$. These, too, were the smallest increases observed in several years, since 1974 for white births and since 1973 for black births.

The rate of childbearing by unmarried women increased by less than 1 percent between 1980 and 1981. In 1981 the nonmarital birth rate was 29.6 births per 1,000 unmarried women 15-44 years of age compared with 29.4 in 1980. Although the 1981 rate was the highest rate ever observed, the increase between 1980 and 1981 was the smallest since 1978 (table 16). The rate for women aged 20-24 years continued to be the highest age-specific rate at 40.9 in 1981, the same as in 1980. The nonmarital childbearing rate for women aged 18-19 years was nearly as high, 39.9.

Again there were differences in the trend in the rates for white and black women. The birth rate for unmarried white women increased by 3 percent, from 17.6 in 1980 to 18.2 in 1981, while the rate for black women declined by 2 percent, from 82.9 to 81.4. The continued converging trends in rates for white and black women in recent years have resulted in a sharp decline in the racial differential in nonmarital birth rates. In 1975 the rate for black women was 7 times the rate for white women. By 1981, this differential had declined to 4.

The relatively modest increases in the number of births to unmarried women between 1980 and 1981 are due both to the considerably smaller increase in the rate of childbearing by unmarried women and to the sharply reduced rate of growth in the number of unmarried women of childbearing age. Increases in age-specific nonmarital birth rates did not exceed 2 percent, while increases in the number of unmarried women were restricted to women aged 20 and older, with the largest increases (7-12 percent) measured for women 25-39 years. Women aged 25 and older typically account for a relatively small portion of all nonmarital births ( 25 percent in 1981). The 1-percent decline in births to unmarried teenagers is the result of a decline of 3 percent in the number of unmarried women 15-19 years old, which more than compensated for the 2-percent increase in their birth rate. By contrast, the 11 -percent increase in non- 1 marital births to women $30-34$ years of age is due to the 12-percent increase in the number of unmarried women in this age group. which occurred while their birth rate declined by 1 percent.

The ratio of births to unmarried women per 1,000 total live births was 189.2 in 1981, 3 percent higher than the ratio of 184.3 in 1980. The ratio for white births was 115.9 and for
black births, 559.5. Numbers of births to unmarried women and ratios for each State, by race, are shown in table 14.

## Interval since last live birth

The date of the mother's last live birth was reported on the birth certificates of 49 States and the District of Columbia in 1981; Texas did not request this information. Intervals between successive births are calculated from the date of the last live birth and the date of the present birth. Interbirth intervals are calculated for all second and higher order births and are shown in table 17.

There was no change in 1981 in the proportion of all second and higher order births occurring at short intervals. In 1981 as in 1980, 13 percent of all births occurred within 18 months of the mother's previous live birth. Similarly, there has been little change in the proportions of births occurring within 2 or 3 years of the mother's previous live birth. In 1981, 28 percent of all second and higher order births occurred within 2 years of the previous live birth and 52 percent occurred within 3 years of the previous birth. (Births occurring at intervals of zero months. that is, the second or later born of multiple births, have been excluded from these calculations.)

Black infants continue to be more likely than white infants to be born at very short intervals. In 1981, 17 percent of black babies compared with 12 percent of white babies followed their mother's previous live birth by less than 18 months. These proportions are unchanged from 1980.

Intervals between successive births tend to be shorter for young mothers than for older mothers. For example, 58 percent of second births to mothers $18-19$ years of age followed the mother's first birth by less than 24 months compared with 33 percent for mothers $20-24$ years of age and 12 percent for mothers aged 35-39 years.

## Educational attainment of mother and father

In 1981 as in 1980 educational attainment of parents was reported on the birth certificates of 47 States and the District of Columbia. The proportions of mothers and fathers with at least a high school diploma continued the steady increase in 1981 that has been observed annually since 1969 when this information first became available. In 1981, 77 percent of mothers and 83 percent of fathers had completed at least 12 years of schooling (table 18). Births to very well-educated parents accounted for an increasing fraction of all births in 1981: 15 percent of mothers and 23 percent of fathers had completed at least 4 years of college. During these years there has also been a steady decline in the proportion of mothers and fathers with only a grade school education or less. In 1981 just 4 percent of mothers and fathers had completed 8 or fewer years of school. The median years of school completed by mothers in 1981 was 12.6 and by fathers, 12.8 .

Both white and black mothers continued to make gains in
their educational attainment in 1981, but a large racial differential still persists in the number of years of school completed. In 1981, 80 percent of white births and 65 percent of black births were to mothers who had completed high school.

Educational attainment tends to be greater as age of mother advances through ages $30-34$ years (table 19). There was relatively little change between 1980 and 1981 in the median years of school completed by mother at each age, except for mothers aged $30-34$ years for whom the median increased from 13.5 years to 13.8 years of school. This increase is consistent with the pattern of delayed childbearing that has been observed in recent years for older, well-educated mothers. ${ }^{1}$

## Month of pregnancy prenatal care began

There was no change in 1981 in the proportion of mothers who began prenatal care in the first trimester of pregnancy. As in 1980, 76 percent of births were to mothers whose prenatal care commenced in the first trimester. The proportion of mothers who did not begin to receive prenatal care until the third trimester (delayed care) or received no care at all stayed at 5 percent in 1981 (tables 20 and 21).

There continues to be a substantial racial differential in the receipt of prenatal care. The proportions of white and black mothers receiving early and delayed or no care changed little between 1980 and 1981. In 1981, 79 percent of white mothers began care in the first trimester and 4 percent received delayed or no care, while 62 percent of black mothers began care early and 9 percent received delayed or no care. This was the first year since 1969, when these data first became available, that the percent of black mothers beginning prenatal care in the first trimester did not increase.

Between 1980 and 1981 there were declines in the proportions of women receiving early care for all age groups from ages 15-19 through 25-29. with the declines relatively greater among teenagers 15-19 years of age. Conversely, increases in the proportions of women receiving delayed or no care were observed for women through ages 25-29. with the greatest relative increase again noted for teenagers. Mothers aged 30 years and over made gains in the proportions receiving early care.

## Number of prenatal visits

The median number of visits made for prenatal care by mothers having any care was 11.4 visits in 1981 compared with the 1980 median of 11.2 . The median for white mothers also increased, from 11.6 in 1980 to 11.7 in 1981, while the median for black mothers was unchanged at 10.2 visits. (Basic data are presented in table 21.) Data on the number of prenatal visits were reported in 1981 by 48 States and the District of Columbia.

The median number of prenatal visits is closely related to the trimester of pregnancy during which prenatal care began (table 21). Early care is associated with more visits than is late care. Mothers beginning care in the first trimester averaged $2^{1 / 2}$
times as many visits as mothers whose care did not commence until the third trimester, 12.2 visits compared with 4.8 visits. Between 1980 and 1981 there were slight increases in the median number of visits for both white and black mothers beginning care in each trimester, except for white mothers whose care began in the first trimester for whom there was no change.

## Period of gestation

The length of gestation, measured from the first day of the mother's last normal menstrual period (LMP) to the date of birth, was reported on the birth certificates of 49 States and the District of Columbia in 1981. New Mexico did not report this information. Prior to 1981 the period of gestation was computed only when there was a valid month, day, and year of LMP. Length of gestation could not be determined for a substantial number of live births each year because the day of LMP was missing. In 1981, for example, 16 percent of the birth certificates reported the month and year of LMP but not the day. Beginning in 1981, weeks of gestation are imputed for records with missing day of LMP when there is a valid month and year reported. These records are assigned a gestational period in weeks using the reported month and year of LMP and the birth weight. A more complete discussion of this procedure and its implications are contained in a previous report. ${ }^{3}$

The effect of the imputation procedure is to increase slightly the proportion of preterm births (less than 37 weeks' gestation) and to lower the proportion of births at $39,40,41$, and 42 weeks of gestation. This tendency is more pronounced for black than for white births, because weeks of gestation were imputed for a much larger portion of black births ( 22 percent) than of white births ( 14 percent). In 1981, 9.4 percent of all babies were born prior to 37 weeks of gestation (table 22). If only the records with a completely reported LMP date are considered, the proportion preterm was 9.0 percent. The 1980 proportion preterm was 8.9 percent; thus, most of the increase in the incidence of preterm births can be associated with the implementation of the imputation procedure.

As in prior years, black infants in 1981 were much more likely to be preterm than were white infants, 17.0 percent compared with 7.9 percent. The incidence of low birth weight is closely associated with length of gestation. Among infants born before 37 weeks of gestation, 39.8 percent weighed less than 2,500 grams ( 5 pounds 8 ounces) compared with just 3.2 percent of babies born at term or post term.

When the proportions of low-birth-weight infants according to length of gestation are compared for white and black births, it is evident that two different factors account for the racial differential in low birth weight. The first factor is that while among preterm births the proportions of low birth weight
were nearly the same for white and black infants, 39.2 percent for white and 41.9 percent for black infants, the proportions among term and post-term babies were substantially higher for black ( 6.2 percent) than for white infants ( 2.6 percent). The second factor is that the distribution of black births by period of gestation is relatively unfavorable with respect to low birth weight in comparison with the distribution of white births by gestation. If the distribution of black births according to length of gestation were the same as it is for white births, the proportion of low birth weight among black babies would have been 9.0 percent instead of 12.5 percent. In other words, about half of the racial differential in low birth weight can be attributed to the differences in the distribution of births by gestation. The other half is due to the much higher level of low birth weight among black than among white term and post-term births.

## Apgar score

The Apgar score is a summary measure used to evaluate the newborn infant's overall physical condition at birth. The score is a composite evaluation of five factors-the infant's heart rate, respiratory effort, muscle tone, irritability, and coloreach of which is assigned a value from 0 to 2 . The overall score is the sum of the five values, with a score of 10 being optimum. In 1981, 46 States recorded the score at 1 minute after birth, an increase of 2 States from the 1980 reporting area; 46 States and the District of Columbia reported the 5-minute score, an increase of 3 States compared with the 1980 reporting area.

Data on Apgar scores first became available in 1978. Since then there has been a steady decline in the proportion of births with high scores of 9 or 10 at both 1 and 5 minutes after birth. In 1981, 45.1 percent of 1 -minute scores and 87.6 percent of 5 -minute scores were 9 or 10 (table 23). Black infants were slightly more likely than white infants to receive high scores at 1 minute, while at 5 minutes the converse was true.

Scores of 0 to 3 , indicating a severely depressed status, were assigned to 2.3 percent of all babies at 1 minute and to 0.6 percent of babies at 5 minutes in 1981. These proportions were about the same as in 1980. Black infants were about twice as likely as white infants to receive scores of $0-3$ at 1 and 5 minutes. A large portion of this racial differential is probably associated with the comparable racial difference in the occurrence of low birth weight, which is very closely associated with unfavorable Apgar scores.

Generally, Apgar scores tended to improve from 1 to 5 minutes after birth, except where the 1 -minute scores were already optimum (table 24 ). Black infants with low 1 -minute scores, however, were somewhat less likely than white infants to improve at 5 minutes. This probably reflects the long-term impact of their lower birth weights.

## List of tables

1. Live births, birth rates, and fertility rates, by race of child:
United States, specified years 1940-55 and each year
1960-81
2. Live births by age of mother, live-birth order, and race of
child: United States, 1981 ..... 12
3. Birth rates by age of mother, live-birth order, and race of child: United States, 1981 ..... 14
4. Total fertility rates and birth rates by age of mother, by race of child: United States, 1970-81 ..... 15
5. Birth rates by live-birth order and race of child: United States, 1970-81 ..... 16
6. Live births by race of child and birth rates: United States, each division and State, 1981 ..... 17
7. Live births by sex and sex ratio, by race of child: United States, 1970-81 ..... 18
8. Live births by race of child and observed and seasonallyadjusted birth and fertility rates, by month: United States,1981.19
9. Live births by attendant and place of delivery, by race of child: United States, 1981 ..... 20
10. Live births and percent distribution of live births by place ofdelivery and attendant, by race of child: United States,1975-8121
11. Live births by age of father, age of mother, and race of child: United States, 1981 ..... 23
12. Birth rates by age of father and race of child: United States, 1970-81 ..... 24
13. Number and percent low birth weight and live births by birthweight, by age of mother and race of child: United States,198125
14. Number and percent of births of low birth weight and number and ratio of births to unmarried women, by race of child: United States and each State, 1981
15. Numbers, rates, and ratios of births to unmarried women, by age of mother and race of child: United States, 1981...28
16. Birth rates for unmarried women by age of mother and race of child: United States, 1970-81 ..... 29
17. Live births by interval since last live birth, live-birth order, and race of child: Total of 49 reporting States and the District of Columbia, 1981
18. Live births by educational attainment of mother and father and race of child: Total of 47 reporting States and the District of Columbia, 198132
19. Live births by educational attainment of mother, age of mother, and race of child: Total of 47 reporting States and the District of Columbia, 1981
20. Live births by month of pregnancy prenatal care began, age
of mother, and race of child: United States, 1981
21. Live births by number of prenatal visits, month of pregnancy prenatal care began, and race of child: Total of 48 reporting States and the District of Columbia, 1981
22. Live births by birth weight, period of gestation, and race of
child: Total of 49 reporting States and the District of
Columbia, 1981 ..... 36
23. Live births by 1 - and 5 -minute Apgar scores, by race of child: Total of reporting States, 1981 ..... 37
24. Live births by 1-minute Apgar score, 5-minute Apgar score, and race of child: Total of 46 reporting States, 1981 ..... 38

Table 1. Live births, birth rates, and fertility rates, by race of child: United States, specified years 1940-55 and each year 1960-81
[Birth rates per 1,000 population in specified group. Fertility rates per 1,000 women aged $15-44$ years in specified group. Population enumerated as of April 1 for census years and estimated as of July 1 for all other years. Beginning 1970 excludes births to nonresidents of the United States]

## Less than 2,500 grams.

${ }^{2}$ Equivalents of the gram weight in terms of pounds and ounces are as follows:
Under 500 grams $=1$ pound 1 ounce or less
500-999 grams $=1$ pound 2 ounces-2 pounds 3 ounces
1,000-1,499 grams $=2$ pounds 4 ounces -3 pounds 4 ounce
1,500-1.999 grams $=3$ pounds 5 ounces -4 pounds 6 ounces
2,000-2,499 grams $=4$ pounds 7 ounces -5 pounds 8 ounces
$2,500-2.999$ grams $=5$ pounds 9 ounces -6 pounds 9 ounces
3,000-3,499 grams $=6$ pounds 10 ounces- 7 pounds 11 ounces
$3,500-3,999$ grams $=7$ pounds 12 ounces- 8 pounds 13 ounces
$4,000-4.499$ grams $=8$ pounds 14 ounces -9 pounds 14 ounces
$4,500-4,999$ grams $=9$ pounds 15 ounces -11 pounds 0 ounces
5,000 grams or more $=11$ pounds 1 ounce or more

Table 14. Number and percent of births of low birth weight and number and ratio of births to unmarried women, by race of child: United States and each State, 1981

[^7]Table 15. Numbers, rates, and ratios of births to unmarried women, by age of mother and race of child: United States, 1981
[Based on 100 percent of births in selected States and on a 50-percent sample of births in all other States; see Technical notes. For 41 States and the District of Columbia, marital status of mother is reported on the birth certificate, and for 9 States, mother's marital status is inferred; see Technical notes. Populations estimated as of July 1]

[^14]NOTE: Excludes data for California, Delaware, District of Columbia, Okiahoma, and Texas, which did not require the reporting of both 1 - and 5 -minute Apgar scores,

## Technical notes

## Sources of data

Data shown in this report for 1981 are based on 100 percent of the birth certificates of 44 States that provided data through the Vital Statistics Cooperative Program. These States accounted for 83 percent of all births in the United States in 1981. Data from the remaining areas (Arizona, California, Delaware, the District of Columbia, Georgia, New Mexico, and North Dakota) are based on a 50 -percent sample of birth certificates filed in those areas.

Many of the topics discussed in this brief report are covered in more analytical detail in other reports published by the National Center for Health Statistics. The topics include first births to older mothers, ${ }^{1}$ birth weight, ${ }^{4}$ births to unmarried women, ${ }^{5}$ birth intervals, ${ }^{6}$ prenatal care, ${ }^{7}$ and Apgar score. ${ }^{8}$ Also available are a methodological report on imputing length of gestation ${ }^{3}$ and three brief reports on births of Hispanic parentage. ${ }^{9-11}$ Reports on midwife-attended births, Asian births, and trends in teenage childbearing are in preparation.

## Population denominators

Birth rates for 1981 are based on populations estimated as of July' $1,1981 .{ }^{12}$ The estimates are based on the 1980 census count. The 1980 census counts by race were modified to be consistent with Office of Management and Budget categories and historical categories for birth data. The modification procedures are discussed in detail in a Census Bureau report. ${ }^{13}$

## Births by marital status of mother

Beginning with 1980 data, national estimates of births to unmarried women are derived from two sources. For 41 States and the District of Columbia marital status of mother is reported directly on the birth certificate; for the remaining 9 States, which

[^15]lack such an item, marital status is inferred from a comparison of the child's and parents' surnames. This procedure represents a substantial departure from the method used prior to 1980 to prepare national estimates of births to unmarried women. The previous method assumed that the incidence of births to unmarried women in States with no direct question on marital status was the same as the incidence in reporting States in the same geographic division.

The new method represents an attempt to use related information on the birth certificate to improve the quality of national data on this topic as well as to provide data for the individual nonreporting States. The method is based on a comparison of the child's surname, the mother's present and maiden surnames, and the father's surname. Briefly, a birth is classified as occurring to a married woman if the parents' surnames are the same, or if the child's and father's surnames are the same and the mother's current surname is missing. A birth is classified as occurring to an unmarried woman if the father's name is missing, if the parents` surnames are different, or if the father's and child's surnames are different and the mother's current surname is missing. An analysis of the effect of the methodological change on the date for 1980 indicated that the change had significantly greater impact on the figures for white births, particularly those to mothers aged 20 years and older, than on the figures for other racial or age groups.

## Computation of percent distributions and medians

Births of unknown live-birth order, educational attainment of mother, month of pregnancy prenatal care began, prenatal visits, and birth weight were subtracted from figures for total births used as denominators before percent distributions and medians were computed. Computations of median years of school completed and median number of prenatal visits were based on tabulations of ungrouped data.

This report presents summary tabulations from the final natality statistics for 1981. More detailed tabulations for 1981 will be published in Vital Statistics of the United States, Volume I-Natality. Prior to the publication of that volume, the National Center for Health Statistics will respond to requests for unpublished data whenever possible.
