# Births of Hispanic Parentage, 1985 

by Stephanie J. Ventura, A.M., Division of Vital Statistics

## Introduction

In 1985, 23 States and the District of Columbia reported information on births of Hispanic parentage (table 1). Because the vast majority of the Hispanic population in this country (an estimated 92 percent) resides in these States (the Hispanic reporting area), the birth statistics in this report are believed to be representative of fertility for the Hispanic population in the United States (U.S. Bureau of the Census, in press).

Previous publications have described the demographic and health characteristics of Hispanic births occurring in 1978-84 (NCHS, 1981, 1982, 1983, 1984b, 1985, 1987). Additionally, birth and fertility rates by Hispanic origin for each State were computed for 1980, using population information available only from the decennial census (NCHS, 1983, 1984a).

The number of babies born to Hispanic mothers in the reporting area totaled 372,814 in 1985 (table 1), a 7-percent increase over the number reported in the same States for 1984 $(346,986)$ and an 11 -percent increase over 1983.

Hispanic-origin mothers accounted for 17 percent of the infants born in the reporting area in 1985, a slight rise over 1983 and 1984 (16 percent). Nearly two-thirds of the Hispanic mothers were Mexican; Puerto Rican, Central and South American, and other Hispanic women each accounted for about 10 percent of Hispanic-origin births; and 3 percent of the Hispanic mothers were Cuban.

The reporting of Hispanic origin of the parents on the birth certificate has improved considerably since 1978 , when this information was first tabulated. In 1985 origin of the mother was not available for only 3.6 percent of the births compared with 12.1 percent in 1978. Origin of the father was also better reported in 1985 than in earlier years, but it is still omitted from a substantial number of records, 14.3 percent in 1985 (table 2) compared with 20.2 percent in 1978. For this reason and also because most of the tabulations in this report relate to characteristics of the mother (for example, fertility rates, educa-
tional attainment, marital status), births are classified only by origin of the mother in tables 1 and 3-7 and in the text.

## Race of child

The vast majority of births to Hispanic mothers are white, 95.4 percent in 1985. However, there are substantial variations in the racial composition of births of the various Hispanic groups, as shown in table 3.

## Birth and fertility rates

Birth and fertility rates for the Hispanic population increased in 1985 compared with 1983 and 1984. The rates continued to be higher than for the non-Hispanic population, 50 percent on the average. (See table 4 for 1985 rates.) The increase between 1984 and 1985 was primarily associated with the 3-4 percent rise in rates for Mexicans. The birth rate for the Hispanic population was 23.3 live births per 1,000 population in 1985, 3 percent higher than in 1984 (22.7); for the non-Hispanic population the birth rate was 15.4 in 1985, 1 percent above the rate for 1984 (15.2). The fertility rate for Hispanic women was 94.0 live births per 1,000 women aged 15-44 years, 3 percent higher than in 1984 ( 91.5 ) and 46 percent higher than the rate for non-Hispanic women (64.6).

The birth rate for the Mexican population rose 4 percent, from 22.9 in 1984 to 23.8 in 1985. The rate for Puerto Ricans was 18.2 , for Cubans it was 10.5 , and for "other Hispanics" it was 29.8. Because of sampling variability associated with the populations used to compute these rates, the year-to-year changes in the rates are not statistically significant.

Variations in fertility rates were comparable to those for birth rates. The fertility rate for Mexican women increased 3 percent, from 95.8 to 98.5 . The rate for Puerto Rican women was 66.5 in 1985, the rate for Cuban women was 51.2, and the rate for "other Hispanic" women was 109.0.

The birth and fertility rates presented in this report were computed for the total of 11 States for which the necessary population data by Hispanic origin were available from the U.S. Bureau of the Census. The 11 States were Arizona, California, Colorado, Florida, Illinois, Indiana, New Jersey, New Mexico, New York, Ohio, and Texas. The population data needed to compute these rates for the non-Hispanic population by race were not available. In 1985, 98 percent of the births in the Hispanic reporting area were to residents of these 11 States.

## Age of mother and live-birth order

Teenage childbearing is relatively common among Hispanic women, particularly Mexican and Puerto Rican women. In 1985, 17 percent of births to Mexican mothers and 21 percent of births to Puerto Rican mothers were to women under 20 years of age, similar to the level of teenage births for black nonHispanic women ( 23 percent) but substantially higher than for Cuban ( 7 percent) and white non-Hispanic women (10 percent) (table 5).

Nearly 1 in every 5 births to Mexican mothers was a fourth or higher order birth ( 18.4 percent) in 1985 , the highest proportion observed among any Hispanic or non-Hispanic group (table 6). The proportion of fourth and higher order births varied widely among other groups, from 5.5 and 7.5 percent for births to Cuban and white non-Hispanic women to 11.0-14.1 percent for births to other specific Hispanic and black non-Hispanic women.

## Births to unmarried mothers

Unmarried mothers accounted for 3 in 10 births to Hispanic women in 1985 (table 6), but the proportions for individual origin groups differed considerably, ranging from 16 percent of Cuban-origin births to 51 percent of Puerto Rican-origin births. The comparable proportions for non-Hispanic births were 12 percent for white and 61 percent for black births. These proportions have risen steadily for both Hispanic and non-Hispanic women in recent years.

As would be expected, nonmarital childbearing is much more frequent among teenage mothers than among mothers aged 20 years and older, regardless of origin group (table 7). Among Hispanic teenagers, the proportions of nonmarital births ranged from 37 percent for Cuban to 74 percent for Puerto Rican women; among non-Hispanic teens, 43 percent of white births and 90 percent of black births were to unmarried women.

The proportions of nonmarital births were considerably lower for all origin groups for ages 20 years and older. They ranged from 15 to 45 percent among Hispanic women compared with 9 percent for white non-Hispanic and 52 percent for black non-Hispanic women.

## Educational attainment of mother

The available data indicate that the educational attainment of Hispanic mothers has risen considerably in recent
years, although it is still substantially below that of nonHispanic mothers (table 6). Because educational attainment is not reported on the birth certificates in California and Texas, data are available for only 35 percent of all Hispanic births and only 15 percent of Mexican births in 1985 . Overall, 56 percent of Hispanic-origin mothers giving birth in 1985 had completed high school compared with 84 percent of white non-Hispanic mothers and 67 percent of black non-Hispanic mothers. The proportions for specific Hispanic groups ranged from 41 percent for Mexican mothers to 79 percent for Cuban mothers. The largest gain in educational attainment was measured for Puerto Rican mothers, among whom 53 percent of those giving birth in 1985 had completed high school compared with 45 percent in 1980.

## Country of birth

Among Hispanic women giving birth in 1985, 45 percent were born in the United States and 55 percent in Puerto Rico or countries outside the United States (table 6). There continue to be wide variations in the proportions of U.S.-born mothers among the various origin groups, from 47 and 51 percent for Mexican and Puerto Rican women to 3 percent for Central and South American women. These proportions are somewhat higher for teenage mothers than for older mothers (table 7).

On the average, U.S.-born Hispanic mothers are about twice as likely to be teenaged as are foreign- or Puerto Ricanborn Hispanic mothers (data are not shown in this report). U.S.-born Hispanic women are somewhat more likely to have completed high school than their foreign- or Puerto Rican-born counterparts, a pattern that has been observed for several years (NCHS, 1987; Ventura and Taffel, 1985).

## Prenatal care

Data on prenatal care and selected measures of the health of newborn infants show that although Hispanic mothers (except Cubans) begin prenatal care later than white non-Hispanic mothers, the levels of low birth weight and low Apgar scores are comparable (table 6). Overall, 61 percent of Hispanic mothers and black non-Hispanic mothers began prenatal care in the first trimester of pregnancy in 1985 compared with 82 percent of white non-Hispanic mothers. The proportions for specific origin groups ranged from 58 percent for Puerto Rican women to 83 percent for Cuban women. Of all Hispanic mothers, 12 percent received delayed prenatal care (beginning in the third trimester of pregnancy) or no care (a range of 4 to 16 percent). Regardless of origin, teenage mothers are less likely to begin prenatal care early and more likely to receive delayed or no care than are older mothers (table 7). Levels of delayed or no care were highest for Puerto Rican teenage mothers (21 percent) and were substantial for other Hispanic-origin groups (except Cubans) as well (16-19 percent).

## Birth weight, Apgar scores, and preterm birth

In spite of their relatively less favorable status with respect to receipt of prenatal care, births to Hispanic women have levels of low birth weight and low Apgar scores that are comparable to those of babies born to white non-Hispanic mothers, as indicated above. In 1985, 6.2 percent of Hispanic babies weighed less than 2,500 grams at birth ( 5 pounds 8 ounces) compared with 5.6 percent of white non-Hispanic infants and 12.4 percent of black non-Hispanic infants (table 6). The proportions for specific Hispanic groups ranged from 5.7 percent for Central and South American babies to 8.7 percent for Puerto Rican babies. The proportions of infants with 1-minute Apgar scores less than 7 averaged 8.3 percent for Hispanic babies compared with 8.9 percent of white non-Hispanic and 11.9 percent of black non-Hispanic infants. Low 5 -minute Apgar scores were reported for 1.6 percent of Hispanic babies compared with 1.5 percent of white non-Hispanic and 3.1 percent of black non-Hispanic babies.

Preterm birth (less than 37 weeks of gestation) was reported for 11 percent of all Hispanic infants compared with 8 percent of white non-Hispanic and 17 percent of black non-Hispanic infants. The proportions of preterm births among Hispanic babies ranged from 9 percent (Cuban) to 13 percent (Puerto Rican).

In an effort to clarify the relationships between Hispanic origin and levels of low birth weight, the birth weight data were further classified by the age of the mother (table 7) and by the month of pregnancy in which prenatal care began and the educational attainment of the mother (data are not shown in this report). Levels of low birth weight were lower for infants whose mothers were aged 20 years and older, who began prenatal care early, and who were high school graduates. But even for babies born to teenagers, to women with delayed or no prenatal care, or to women who did not complete high school, the proportions of low-weight infants were still relatively favorable for Hispanic-origin, especially Mexican, babies. It is difficult to account for this pattern, one that has been observed for several years. One factor may be the much lower incidence of smoking among Hispanic than among non-Hispanic women. Unpublished data from the 1980 National Natality Survey conducted by the National Center for Health Statistics (NCHS) show that only 10 percent of Mexican women, compared with 27 percent of white non-Hispanic women, smoked during pregnancy. Information from the 1985 National Health Interview Survey, also conducted by NCHS, confirms a significantly lower rate of smoking among Hispanic women (NCHS, in press).

${ }^{1}$ Includes origin not stated.
${ }^{2}$ Includes races other than white and black.
${ }^{3}$ Excludes data for California and Texas, which did not report educational attainment.
${ }^{4}$ Birth weight of less than 2,500 grams ( 5 lb .8 oz .).

## Technical notes

## Sources of data

Concurrent with the 1978 revision of the U.S. Standard Certificate of Live Birth, the National Center for Health Statistics recommended that States add items to identify the Hispanic or ethnic origin of the newborn's mother and father. In 1985, 23 States and the District of Columbia included questions on origin, selecting one of two basic formats. The first format was an open-ended item to obtain the specific origin or descent of each parent (for example, Italian, Mexican, German, Puerto Rican, English, or Cuban). The second format was directed toward the Hispanic population and asked whether the mother and father were of Spanish origin. If so, the specific origin, such as Mexican, Puerto Rican, or Cuban, was to be indicated.

Birth data shown in this report are based on 100 percent of the births occurring in the 23 reporting States and the District of Columbia. The data shown in the tables are for births to all residents of the reporting area, regardless of where the births occurred. Births occurring in nonreporting States to residents of the reporting area are included in the "not stated" origin category.

## Racial classification

Racial designation in this report is that of the child, which is determined from the race of the parents as entered on the birth certificate. When the parents are of different races and one parent is white, the child is assigned the other parent's race. When the parents are of different races and neither parent is white, the child is assigned the father's race with one ex-ception-if the mother is Hawaiian or part-Hawaiian, the child is considered Hawaiian. When race is missing on the certificate for one parent, the child is assigned the race of the other parent. When race is not reported for either parent, the child is assigned the race of the child on the immediately preceding record.

## Population denominators

Birth and fertility rates for 1985 are based on estimates of the Hispanic population from the Current Population Survey
(CPS). The populations used to compute the rates in this report for 1985 were derived by averaging the CPS estimates for 1984 and 1986 because estimates of the Hispanic population for selected States and subgroups for 1985 are believed questionable. Beginning with 1986, the CPS figures include estimates of undocumented immigrants (U.S. Bureau of the Census, 1987). The effect of this change may be to reduce the levels of the birth and fertility rates by about 1 percent.

Population estimates were provided for 11 States, including Arizona, California, Colorado, Florida, Illinois, Indiana, New Jersey, New Mexico, New York, Ohio, and Texas. These estimates were controlled to postcensal independent estimates of the Hispanic population by age and sex for the United States, based on 1980 census data. The population data are based on small samples and may, therefore, be subject to substantial sampling error. Information on the derivation of these estimates and the sampling error is presented in two U.S. Bureau of the Census reports (1987, in press).

## Computation of rates

In computing birth and fertility rates for this report, births with not-stated origin of mother are included with non-Hispanic births rather than being distributed. Thus, rates for the Hispanic population are underestimates of the true rates to the extent that the births with not-stated origin of mother for the 11-State area ( 2.9 percent) are actually to Hispanic mothers. The population with not-stated origin has been imputed. The effect on the rates is believed to be small.

## Computation of percents and percent distributions

Births with unknown live-birth order, nativity of mother, educational attainment of mother, month of pregnancy in which prenatal care began, birth weight, period of gestation, and 1and 5 -minute Apgar scores were subtracted from total births before percents and percent distributions were computed.
