Foot-and-Mouth Disease

Chris Bostock
Institute for Animal Health
Compton, Pirbright and Edinburgh,
UK

Good science, useful science
Foot-and-mouth Disease Virus.

- FMDV is the causative agent of foot-and-mouth disease, an economically important and highly contagious disease of many domestic livestock, such as pigs, sheep, goats and cattle.

- The primary route of infection by FMDV is through the upper respiratory tract.

- FMDV has a strong predisposition for epithelial cells. The initial sites of virus replication are thought to be epithelial cells of the oropharynx and associated lymphoid tissues.

- During the development of disease, virus is widely disseminated throughout the body with secondary sites of replication in many epithelial tissues.

- Epithelial cells of the soft palate and pharynx are most likely the sites of virus replication in persistently infected animals.
The nine genera that comprise the *Picornaviridae*

- **Genus: Aphthovirus**
  - Foot-and-mouth disease virus
  - Equine rhinitis A virus
  - ERBV
- **Genus: Erbovirus**
  - Equine rhinitis B virus
- **Genus: Cardiovirus**
  - Encephalomyocarditis virus
- **Genus: Teschovirus**
  - Porcine teschovirus
- **Genus: Kobuvirus**
  - Aichi virus
- **Genus: Parechovirus**
  - Human parechovirus
- **Genus: Enterovirus**
  - Poliovirus
  - Human enterovirus A
  - Human enterovirus B
  - Human enterovirus C
  - Human enterovirus D
- **Genus: Rhinovirus**
  - Human rhinovirus A
  - Human rhinovirus B
  - Human rhinovirus C
  - Human rhinovirus D
  - Human rhinovirus E

The UK FMD outbreak 2001
IMPORTANT EVENTS IN THE SPREAD AND CONTROL OF FMD IN THE UK

• 20 Feb - FMD confirmed at abattoir near Brentwood, Essex.
• 23 Feb - Culling on IPs and DCs. National movement restrictions.
• 15 March - Sheep, goats & pigs within 3 km of an IP in Lockerbie, Carlisle and Solway targeted for culling.
• 23 March - Contiguous premises (CPs) were included in the cull.
• 26 March - Epidemic reached its maximum with 54 outbreaks in one day.
• 27 March - 3 km cull started in Penrith valley, Cumbria
• 29 March - 24/48 hour cull policy began, IPs slaughtered within 24 hours CPs culled within 48 hours
• 26 April - cattle in farms with high biosecurity exempted from culls
Stamping out involves:

• identification of infected animals
• culling of infected herds and flocks
• movement restrictions
• tracing of dangerous contacts
• culling of contiguous premises
• safe disposal of culled animals

Good science, useful science
Foot and mouth crisis

Cattle low mightily, then the thuds begin

Killing fields Cumbria fears disease is now uncontrollable

John Vidal

The three slaughtermen are young, cheerful and clear-eyed. Killing is their business and they have never known trade like this. In the spring morning light they were on a farm near Wigton, Cumbria, shooting more than 100 cows and 500 sheep. Now the Ministry of Agriculture has told farmers to go to Jim Hutcheson’s Scale End farm near Penrith.

Our mobile death squad rattle through the lowlands south of Carlisle. We carry, in the back of a 16-year-old white van, cartridges, stun guns, decontamination suits, blue overalls, rubber gloves, sprays, wellington boots, forms and all the paraphernalia of modern slaughter.

The landscape is flat and desolate. Most farms here have been condemned and there are no animals in the field.

The white smoke of incineration pyres drifts into the van. We pass decomposing sheep carcases piled high in the corner of fields where they have been waiting days to be picked up. The sickly stench of death hangs over some farms; in others the cattle and sheep lie sweetly together, their limbs spread in the sun, tongues rigid and out.

Scale End was condemned on Sunday, but in the watery sunlight it seems normal. At the end of a long road is a tangle of ancient and modern buildings. Seven lambs play in a small paddock behind the farm. A bull walks the yard. The cattle low quietly in the barns and the sheep are penned in a field beyond. This is spring; there are daffodils on the roadside, birds in the hedges, and the Hutcheson family is waiting expectantly, as if for a relative.

But we bring only death. The three slaughtermen change into their overalls and white suits. They smoke a cigarette and share a joke. They don’t like this, they say. It is messy and too human. Yesterday a farmer cracked up.

We cross the straw border that separates the clean from the uncleans, and dip our feet in disinfectants. There are handshakes and nods. Mr Hutcheson is almost too emotional to speak, but a toothless old cowherd shows them round. “There are plenty sheep and cattle,” he says.

The slaughtermen reckon several hundred cows and 400 sheep. It will take four hours, they say, and start moving machinery around the barn to prevent the animals try to bolt. Now the cattle squeal and low and the sheep bleat. The legs of a cow give way and it drops to the ground. Five heads stand out of the barn, passed through them. It has not been spotted, they say, because the authorities have not had the resources, or perhaps the will, to check.

But in the next few days it has ominously spread deeper into the Scottish borders, with four cases, and, significantly, into the Scottish Borders where the army also plans a pyre for 15,000 cattle.

31st March 2001
The making of an epidemic

How foot and mouth spread

1. Foot and mouth outbreak at Burnside farm, Heddon-on-the-wall, Northumberland
2. Animals at nearby Prestwick Hall farm, Pontefract, are infected, probably as the virus is carried on the wind
3. 40 sheep from Prestwick Hall are among 3,500 animals sold at Hexham.

The buyer is Willy Cleaver, a Devon farmer.
4. The sheep are shipped to Longtown market, Carlisle, which acts as a holding centre.
5. The sheep are taken to Mr Cleaver's Burdon farm, Highamport in Devon.
6. Sheep from Highamport are taken to Bromham slaughterhouse in Wiltshire where they develop foot and mouth.

7. 348 sheep sent before foot and mouth outbreak was identified were exported from Devon to Germany via Dover. Yesterday they were destroyed as a precautionary measure.

Main points
- Number of confirmed cases stood at 21, with more than 3,500 animals affected in Northumberland, County Durham and west Yorkshire.
- The Department of Agriculture, Fisheries and Food has banned all movements of livestock from the area.
- An 18-year-old woman has been questioned by police over the sale of infected sheep.
- The government has set up a task force to deal with the crisis.
- The European Union has suspended all trade in livestock and livestock products from the UK.

MECHANISMS OF SPREAD OF FMD

• CONTROLLABLE SPREAD
  – movement of infected animals
  – movement of animal products e.g. meat, milk, offal
  – farm equipment, milking machines, vehicles, people etc

• UNCONTROLLABLE SPREAD
  – spread by the carriage of virus on the wind
  – role of wildlife and birds?
AIRBORNE SPREAD FROM HEDDON, NORTHUMBERLAND

Note: Figures are provisional and subject to change.
The need for rapid diagnosis

Good science, useful science
Current diagnostic tests for FMD:

• Antigen detection by ELISA - ~4 hours
• Infectious virus detection through infection of bovine thyroid cells - ~4 days

BUT

• time is taken to get samples to the Laboratory

Future tests may be based on:

• PCR, both laboratory based and portable
• Penside stip tests
The big debate: to vaccinate or not
FMD VACCINES

- FMD vaccines are inactivated, concentrated, purified preparations of virus mixed with an adjuvant.
- All clove-hoofed species can be immunised.
- One dose of emergency vaccine will protect for 4 to 6 months.
- Two doses of commercial vaccines are required to give protection for 6 to 9 months.
- Do not prevent establishment of carrier state.
FMD VACCINATION IN AN EMERGENCY

• Time is taken to identify protective vaccine strain and formulate vaccine.

• If incubating animals are vaccinated then disease can be expected.

• The period from vaccination to protection is 3 to 4 days with a potent emergency vaccine. (With a commercial vaccine the period is 2 to 3 weeks.)

• Re-excretion of virus and spread to animals in-contact can be expected if vaccinated animals are exposed to virus in the period before they become fully immune.
The problem of persistent infections and the carrier state

Good science, useful science
**Duration of FMDV persistence**

(Ruminants only - not pigs)

- **Cattle up to 3.5 years**
  (around 50% of recovered animals are carriers at 4 weeks, but can range from 0-100% depending on the strain of virus and probably the challenge dose. The % decreases over time, but may be up to 40-50% at 6 months, 20% at 8 months and up to 12% at 12 months)

**Sheep up to 9 months**

(about 45-50% of recovered animals are carriers at 8 weeks, 25% are at 12 weeks)

**Goats up to 4 months**

**African buffalo at least 5 years** - about 55-70% may be carriers under free-living conditions

- **Virus levels decline over time - final elimination of persistence?**
ISH-TSA detection of FMDV RNA in persistently infected bovine soft palate tissues
Vaccinated animals or naturally protected animals exposed to live virus may also become infected in the pharynx and develop a subclinical infection but, in many cases, leading to persistent infection.

The % of such animals which become carriers, the virus levels present and the duration of the carrier state have not been shown to be significantly different from non-vaccinated reconvalescent animals (up to 80% carriers have been demonstrated after experimental challenge of vaccinated cattle).
Can vaccines be improved? The ideal vaccine needs to:

- Have wide specificity
- be safe
- be stable
- be “marked” so that vaccinated animals can be distinguished from infected animals
- prevent persistent infections
- give long term immunity
